## Homework Set \#6

5.60

The ionic strength of the solution is

$$
I=\frac{1}{2} \sum_{i} m_{i} z_{i}^{2}=\frac{1}{2}\left[(0.0020 m)(2)^{2}+(0.0040 m)(-1)^{2}\right]=0.0060 m
$$

(a) The activity coefficients of $\mathrm{Mg}^{2+}$ and $\mathrm{Cl}^{-}$can be evaluated using

$$
\log \gamma_{i}=-0.509 z_{i}^{2} \sqrt{I}
$$

For $\mathrm{Mg}^{2+}$

$$
\begin{aligned}
\log \gamma_{+} & =-0.509(2)^{2} \sqrt{0.0060}=-0.158 \\
\gamma_{+} & =0.695=0.70
\end{aligned}
$$

For $\mathrm{Cl}^{-}$,

$$
\begin{aligned}
\log \gamma_{-} & =-0.509(-1)^{2} \sqrt{0.0060}=-3.94 \times 10^{-2} \\
\gamma_{-} & =0.913=0.91
\end{aligned}
$$

(b) The mean ionic activity coefficient is

$$
\gamma_{ \pm}=\left(\gamma_{+}^{v_{+}} \gamma_{-}^{v_{-}}\right)^{1 / v}=\left[(0.695)(0.913)^{2}\right]^{1 / 3}=0.83
$$

5.74 Calculate the solubility of $\mathrm{BaSO}_{4}$ (in $\mathrm{g} \mathrm{L}^{-1}$ ) in (a) water and (b) a $6.5 \times 10^{-5} \mathrm{M} \mathrm{MgSO}_{4}$ solution. The solubility product of $\mathrm{BaSO}_{4}$ is $1.1 \times 10^{-10}$. Assume ideal behavior.

The equation for the dissolution of $\mathrm{BaSO}_{4}$ is

$$
\mathrm{BaSO}_{4}(s) \rightleftharpoons \mathrm{Ba}^{2+}(a q)+\mathrm{SO}_{4}^{2-}(a q)
$$

(a) If the solubility of $\mathrm{BaSO}_{4}$ is $x M$, then there are $x M$ of $\mathrm{Ba}^{2+}$ and $x M \mathrm{SO}_{4}^{2-}$ in the solution.

$$
\begin{aligned}
K_{\mathrm{sp}} & =1.1 \times 10^{-10}=\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{SO}_{4}^{2-}\right]=x \cdot x \\
x & =1.05 \times 10^{-5}
\end{aligned}
$$

Therefore,

$$
\text { the solubility of } \mathrm{BaSO}_{4}=\left(1.05 \times 10^{-5} \mathrm{~mol} \mathrm{~L}-1\right)\left(\frac{233.4 \mathrm{~g}}{1 \mathrm{~mol}}\right)=2.5 \times 10^{-3} \mathrm{~g} \mathrm{~L}^{-1}
$$

(b) The $\mathrm{MgSO}_{4}$ solution contains $6.5 \times 10^{-5} \mathrm{M}$ of $\mathrm{SO}_{4}^{2-}$. If the solubility of $\mathrm{BaSO}_{4}$ is $x M$, then there are $x M$ of $\mathrm{Ba}^{2+}$ and $x+6.5 \times 10^{-5} M \mathrm{SO}_{4}^{2-}$ in the solution.

$$
\begin{aligned}
& K_{\mathrm{sp}}=1.1 \times 10^{-10}=\left[\mathrm{Ba}^{2+}\right]\left[\mathrm{SO}_{4}^{2-}\right]=x\left(x+6.5 \times 10^{-5}\right) \\
& x^{2}+6.5 \times 10^{-5} x-1.1 \times 10^{-10}=0 \\
& x=1.65 \times 10^{-6} \quad \text { or } \quad x=-6.67 \times 10^{-5}(\text { nonphysical })
\end{aligned}
$$

Therefore,

$$
\text { the solubility of } \mathrm{BaSO}_{4}=\left(1.65 \times 10^{-6} \mathrm{~mol} \mathrm{~L}^{-1}\right)\left(\frac{233.4 \mathrm{~g}}{1 \mathrm{~mol}}\right)=3.9 \times 10^{-4} \mathrm{~g} \mathrm{~L}^{-1}
$$

5.75 The thermodynamic solubility product of AgCl is $1.6 \times 10^{-10}$. What is $\left[\mathrm{Ag}^{+}\right]$in (a) a 0.020 $M \mathrm{KNO}_{3}$ solution and (b) a 0.020 M KCl solution?
(a) First calculate the ionic strength and the mean ionic activity coefficient of the $\mathrm{KNO}_{3}$ solution. Since this solution is dilute, its molality has the same numerical value as its molarity. For this solution, $z_{+}=1, z_{-}=-1, m_{+}=m_{-}=0.020 \mathrm{~m}$.

$$
\begin{aligned}
I & =\frac{1}{2}\left[(0.020 \mathrm{~m})(1)^{2}+(0.020 \mathrm{~m})(-1)^{2}\right]=0.020 \mathrm{~m} \\
\log \gamma_{ \pm} & =-0.509|(1)(-1)| \sqrt{0.020}=-7.20 \times 10^{-2} \\
\gamma_{ \pm} & =0.847
\end{aligned}
$$

The molalities of $\mathrm{Ag}^{+}\left(m_{+}\right)$and $\mathrm{Cl}^{-}\left(m_{-}\right)$are the same. $m_{+}$is calculated from $K_{\text {sp }}^{0}$ and $\gamma_{ \pm}$:

$$
\begin{aligned}
K_{\mathrm{sp}}^{\mathrm{o}}=1.6 \times 10^{-10} & =a_{+} a_{-}=\gamma_{+} m_{+} \gamma_{-} m_{-} \\
& =\gamma_{ \pm}^{2} m_{+}^{2} \\
& =(0.847)^{2} m_{+}^{2} \\
m_{+} & =1.5 \times 10^{-5}
\end{aligned}
$$

Since the concentration of Ag is very small, its molarity has the same numerical value as its molality. Thus, $\left[\mathrm{Ag}^{+}\right]=1.5 \times 10^{-5} \mathrm{M}$.
(b) The ionic strength of the $0.020 \mathrm{M} \mathrm{KCl}(\approx 0.020 \mathrm{~m})$ solution is the same as the $0.020 \mathrm{M} \mathrm{KNO}_{3}$ solution in (a). However, when AgCl dissolves in this solution, the molalities of $\mathrm{Ag}^{+}\left(m_{+}\right)$and $\mathrm{Cl}^{-}\left(m_{-}\right)$are no longer the same, as KCl contributes extra Cl${ }^{-}$. In fact, $m_{-}=m_{+}+0.020 \mathrm{~m}$.

$$
\begin{aligned}
K_{\mathrm{sp}}^{\mathrm{o}}=1.6 \times 10^{-10} & =a_{+} a_{-}=\gamma_{+} m_{+} \gamma_{-} m_{-} \\
& =\gamma_{ \pm}^{2} m_{+} m_{-} \\
& =(0.847)^{2} m_{+}\left(m_{+}+0.020\right) \\
m_{+}\left(m_{+}+0.020\right) & =2.23 \times 10^{-10}
\end{aligned}
$$

Since $m_{+}$is expected to be much smaller than $0.020, m_{+}+0.020 \approx 0.020$. Therefore,

$$
\begin{aligned}
m_{+}(0.020) & =2.23 \times 10^{-10} \\
m_{+} & =1.1 \times 10^{-8}
\end{aligned}
$$

Indeed, $m_{+}$is insignificant compared with 0.020 .

Since the concentration of $\mathrm{Ag}^{+}$is very small, its molarity has the same numerical value as its molality. Thus, $\left[\mathrm{Ag}^{+}\right]=1.1 \times 10^{-8} \mathrm{M}$.
5.78 A 0.010 m aqueous solution of the ionic compound $\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}_{3}$ has a freezing-point depression of 0.0558 K . What can you conclude about its structure? Assume the compound is a strong electrolyte.

The van't Hoff factor is

$$
i=\frac{\Delta T}{K_{\mathrm{r}} m_{2}}=\frac{0.0558 \mathrm{~K}}{\left(1.86 \mathrm{~K} \mathrm{~mol}^{-1} \mathrm{~kg}\right)\left(0.010 \mathrm{~mol} \mathrm{~kg}^{-1}\right)}=3.0
$$

There are 3 particles in the solution per 1 particle before dissociation. Thus, the compound is probably $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right] \mathrm{Cl}_{2}$, which on dissolution, dissociates into $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Cl}\right]^{2+}$ and $2 \mathrm{Cl}^{-}$.
