94-775/95-865 Lecture 5: Clustering Part I

George Chen

Announcements

- HW1 solutions are up in Canvas (look in “Files”)

- HW2 is now due Friday February 15

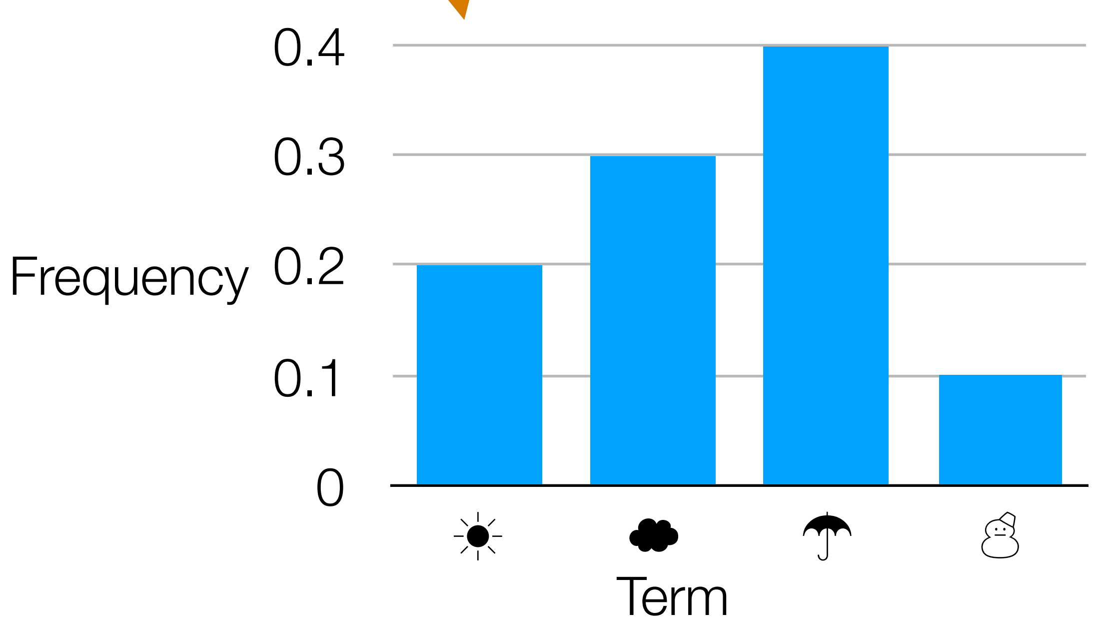
- The t-SNE recitation you were supposed to have today is available as a video on Canvas: “UDAP 01/25 Recitation”

Let’s look at images

(Flashback) Recap: Basic Text Analysis

- Represent text in terms of "features"
  (such as how often each word/phrase appears)
  - Can repeat this for different documents:
    represent each document as a "feature vector"

"Sentence": ☀☂☁☁☁☂⛄☂☂☀



$$\begin{bmatrix} 0.2 \\ 0.3 \\ 0.4 \\ 0.1 \end{bmatrix}$$

This is a point in 4-dimensional space, $\mathbb{R}^4$

dimensions = number of terms

In general (not just text): first represent data as feature vectors

Example: Representing an Image

Go row by row and look at pixel values

0: black
1: white

$$\begin{bmatrix} 0 & & \\ & & \\ & & \end{bmatrix}$$

Image source: starwars.com

Example: Representing an Image

0: black
1: white

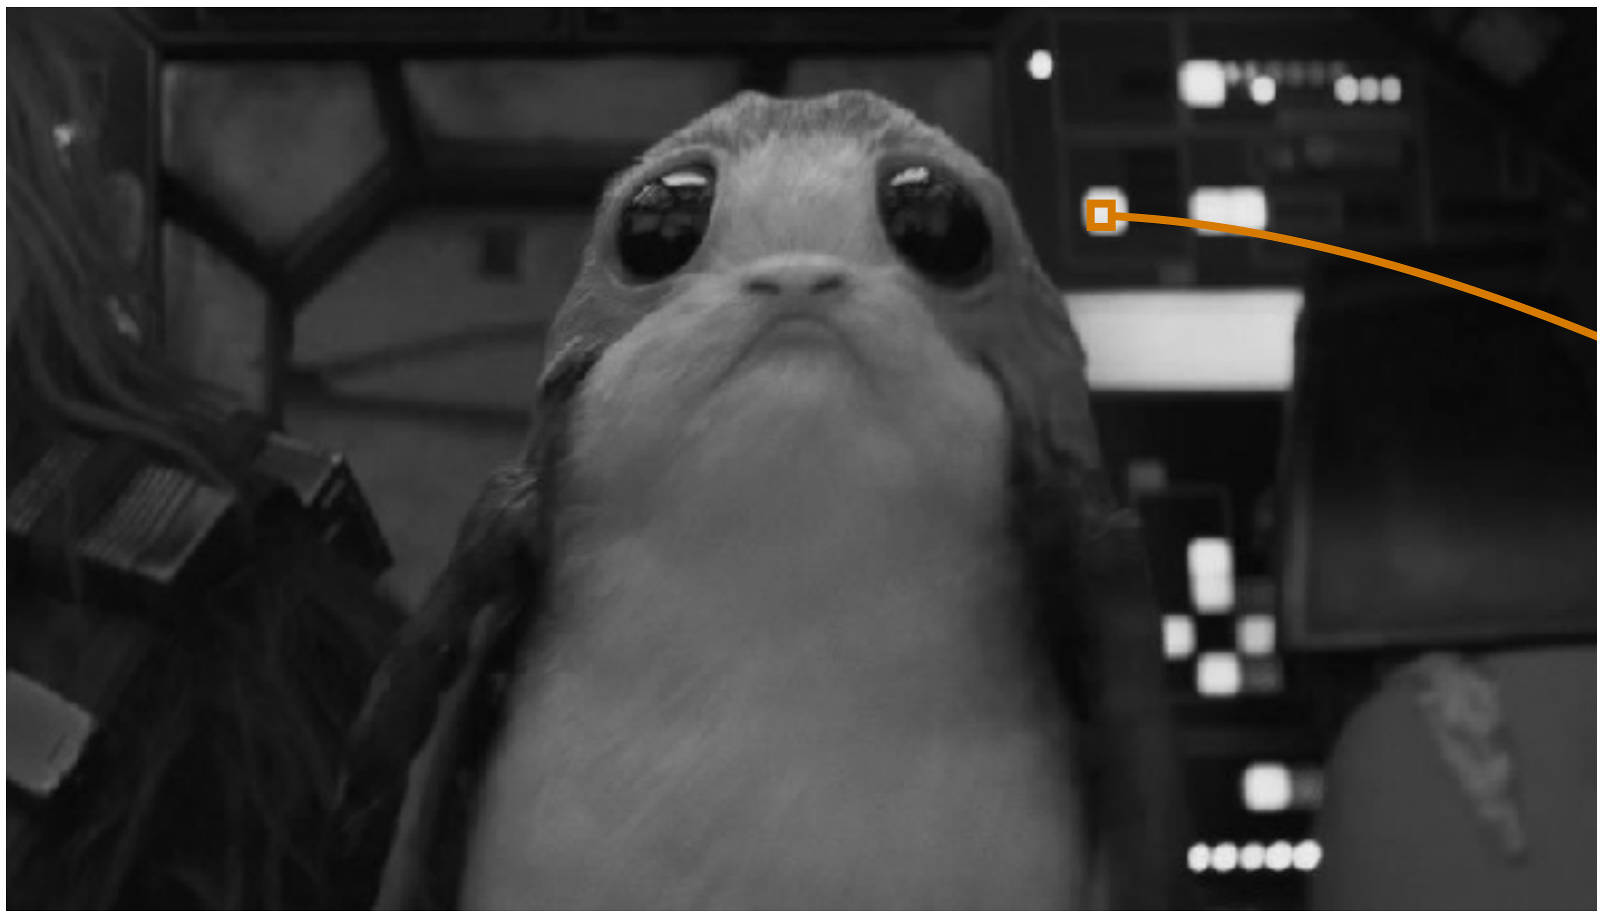
$$\begin{bmatrix} 0 \\ 0 \\ \vdots \\ \\ \\ \\ \end{bmatrix}$$

Go row by row and look at pixel values

Image source: starwars.com

Example: Representing an Image

0: black
1: white



$$\begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0.9 \\ \vdots \\ \\ \\ \end{bmatrix}$$

Go row by row and look at pixel values

Image source: starwars.com

Example: Representing an Image

0: black
1: white

$$\begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0.9 \\ \vdots \\ \\ 0.3 \end{bmatrix}$$

Go row by row and look at pixel values

dimensions = image width × image height

Very high dimensional!

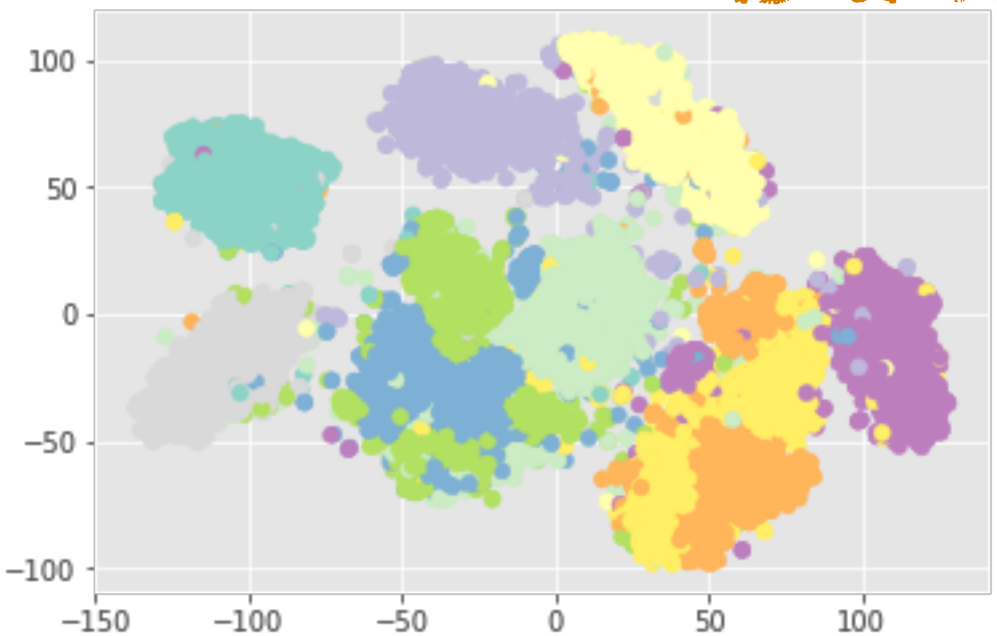
Image source: starwars.com

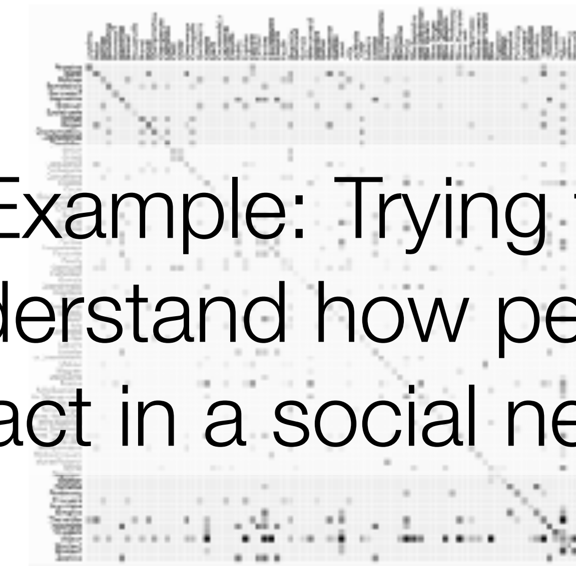
Dimensionality Reduction for Images

Demo

Visualization

is a way of debugging data analysis!





Example: Trying to understand how people interact in a social network

Important:
Handwritten digit demo is a **toy example** where we know which images correspond to digits 0, 1, … 9

Many real UDA problems:
The data are **messy** and it’s not obvious what the “correct” labels/answers look like, and “correct” is ambiguous!

This is largely why I am covering “supervised” methods (require labels) *after* “unsupervised” methods (don’t require labels)

Top right image source: https://bost.ocks.org/mike/miserables/

Let's look at a *structured* dataset
(easier to explain clustering):
drug consumption data

Drug Consumption Data

Demo

Clustering Shows Up Often in Real Data!

- Example: crime might happen more often in specific hot spots
- Example: people applying for micro loans have a few specific uses in mind (education, electricity, healthcare, etc)
- Example: users in a recommendation system can share similar taste in products
- Example: students have different skill levels (clusters could correspond to different letter grades)

To come up with clusters, we first need to define what it means for two things to be "similar"

The Art of Defining Similarity

- There usually is no “best” way to define similarity

Example: cosine similarity $\frac{\langle Y_u, Y_v \rangle}{\| Y_u \| \| Y_v \|}$

- Also popular: define a distance first and then turn it into a similarity

Example: Euclidean distance $\| Y_u - Y_v \|$

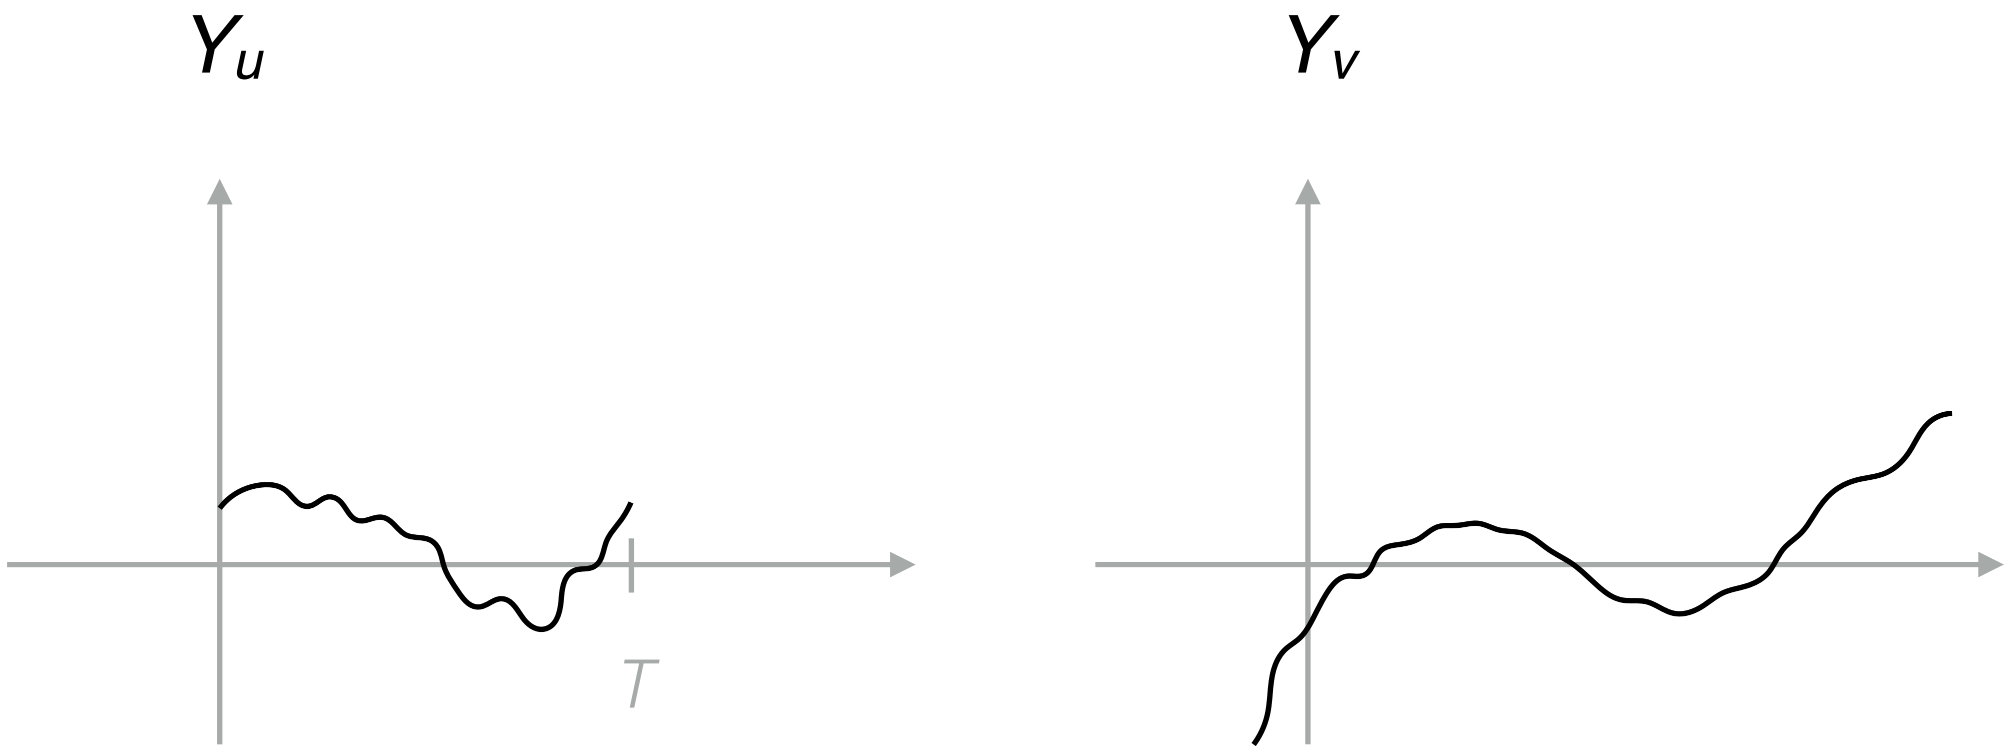
Turn into similarity with decaying exponential $\downarrow$

$\exp(-\gamma \| Y_u - Y_v \|)$

where $\gamma > 0$

Example: Time Series

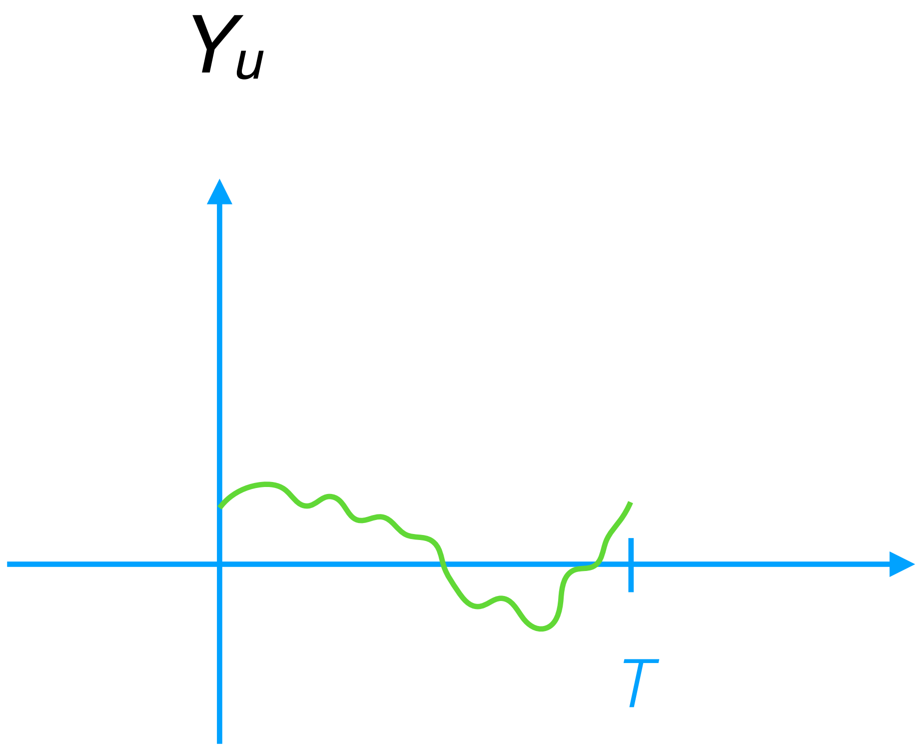
How would you compute a distance between these?



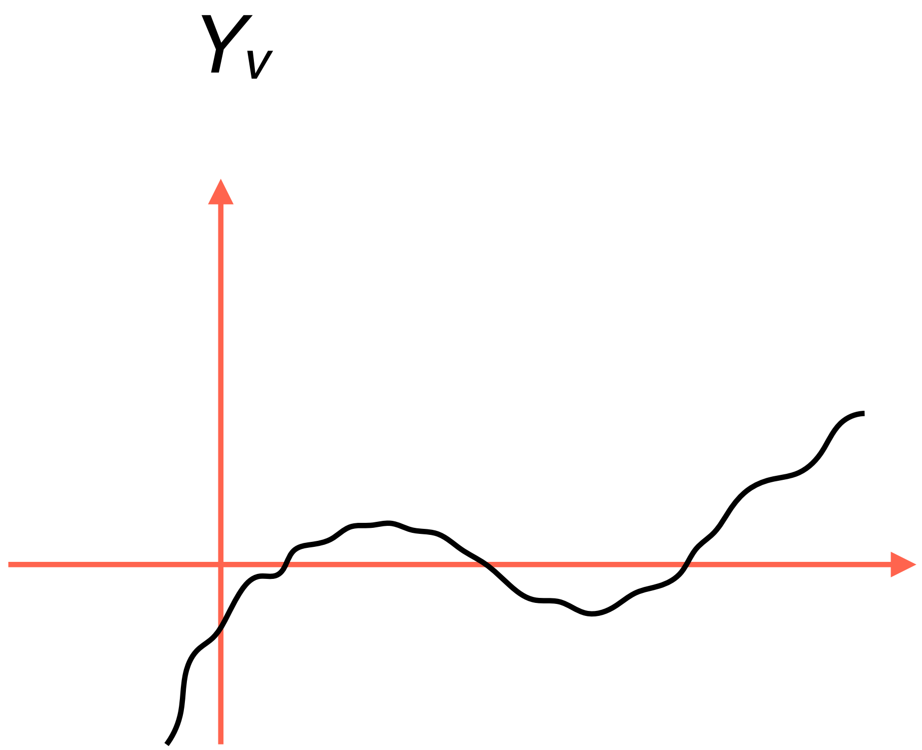
Only observe time steps
between 0 and T

Example: Time Series

How would you compute a distance between these?

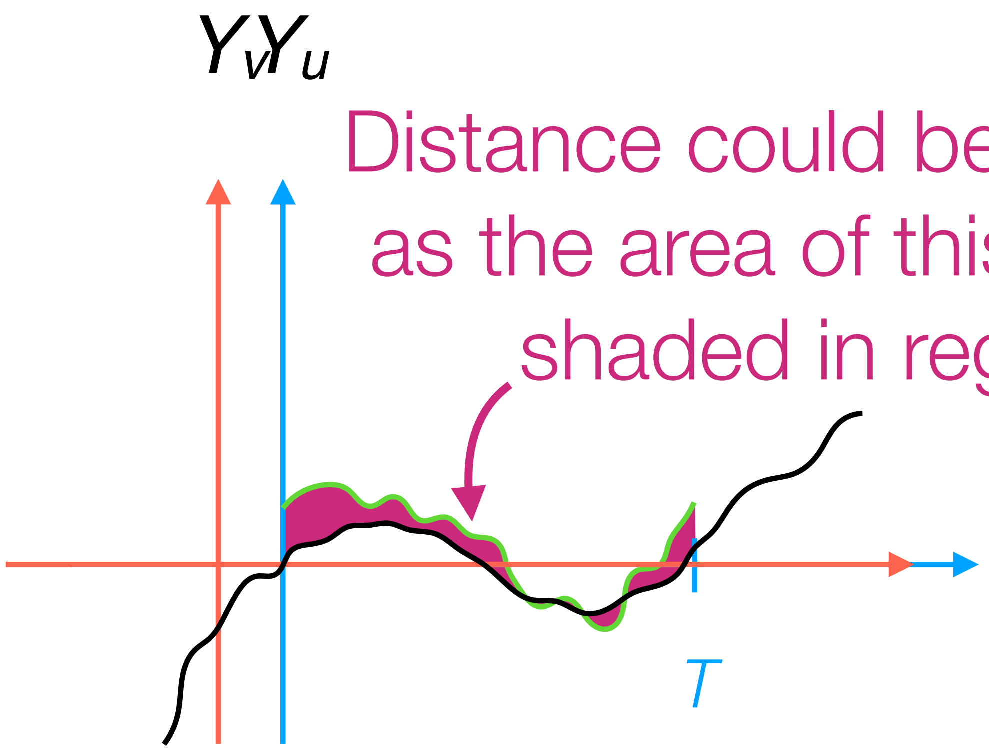


Only observe time steps between 0 and T



Example: Time Series

How would you compute a distance between these?



One solution: Align them first

In practice: for time series, very popular to use "dynamic time warping" to first align (it works kind of like how spell check does for words)

Is a Similarity Function Any Good?

Easy thing to check:

- Pick a data point
- Compute its similarity to all the other data points, and sort them from most similar to least similar
- Inspect the most similar data points

If the most similar points are not interpretable, it's quite likely that your similarity function isn't very good =(

Going from Similarities to Clusters

There's a whole zoo of clustering methods

Two main categories we'll talk about:

Generative models

1. Pretend data generated by specific model with parameters

2. Learn the parameters ("fit model to data")

3. Use fitted model to determine cluster assignments

We start here

Hierarchical clustering

Top-down: Start with everything in 1 cluster and decide on how to recursively split

Bottom-up: Start with everything in its own cluster and decide on how to iteratively merge clusters

We're going to start with perhaps the most famous of clustering methods

It won't yet be apparent what this method has to do with generative models

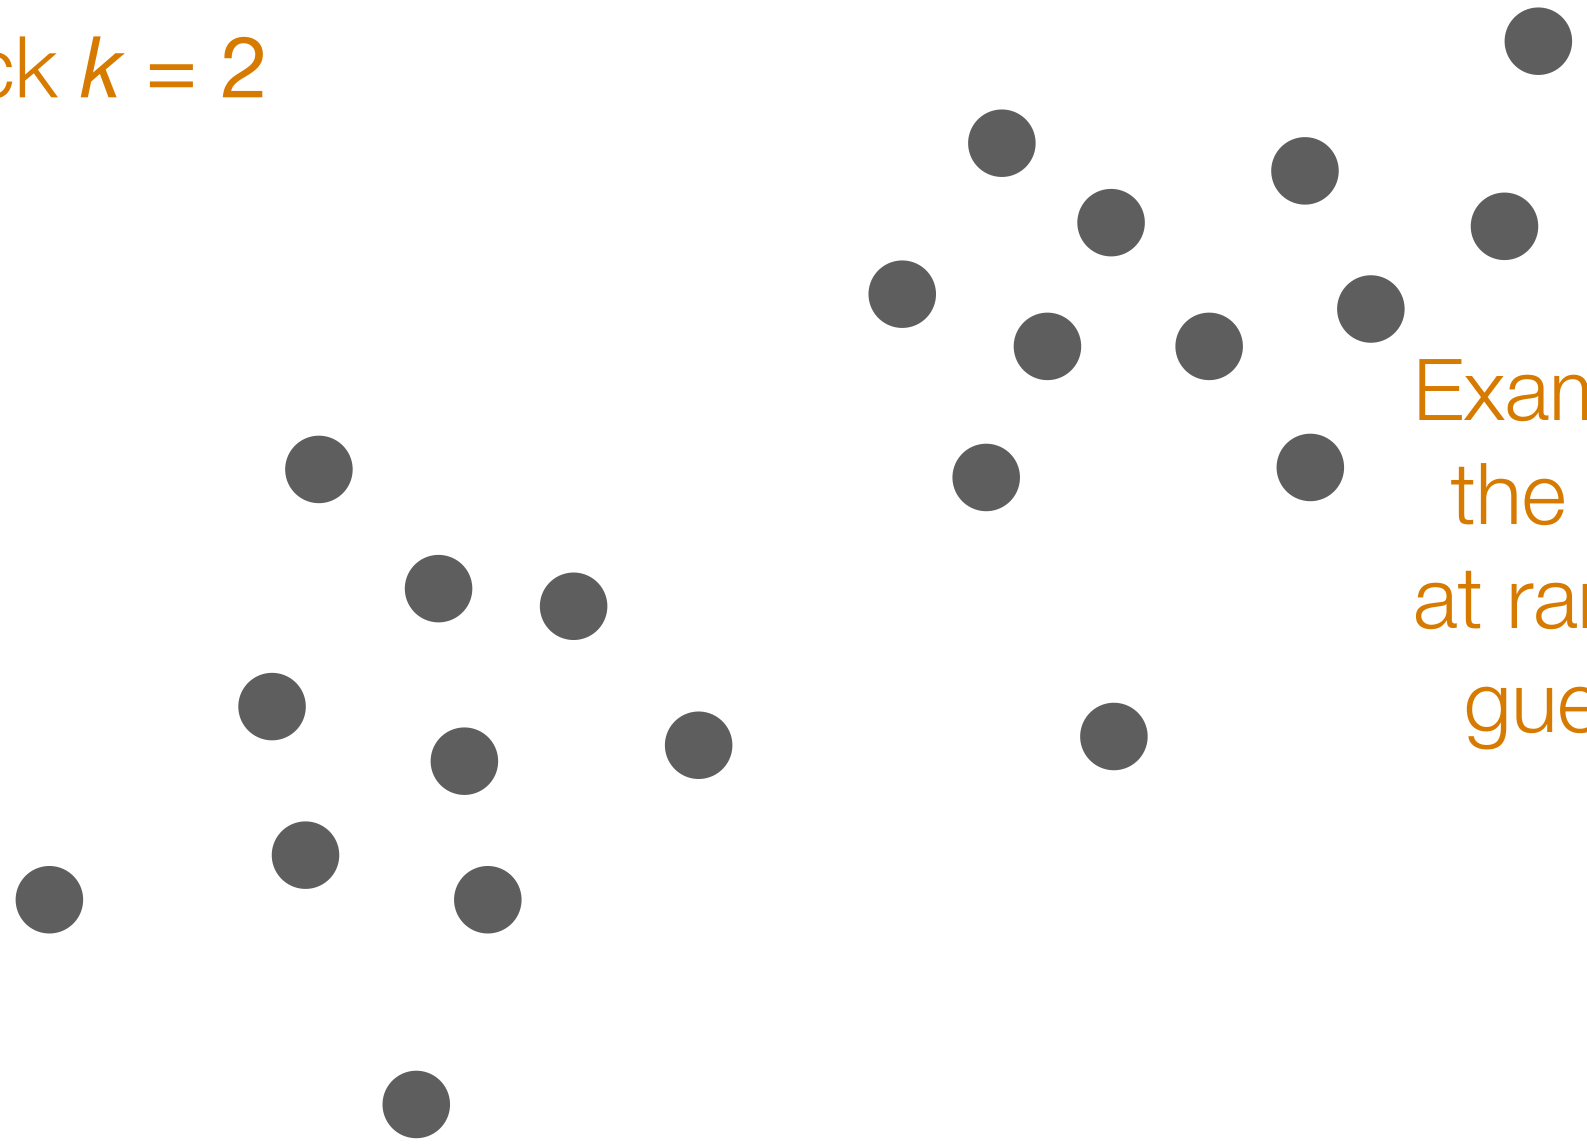
k-means

Step 0: Pick *k*

We'll pick *k* = 2

Step 1: Pick <u>guesses</u> for where cluster centers are

Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

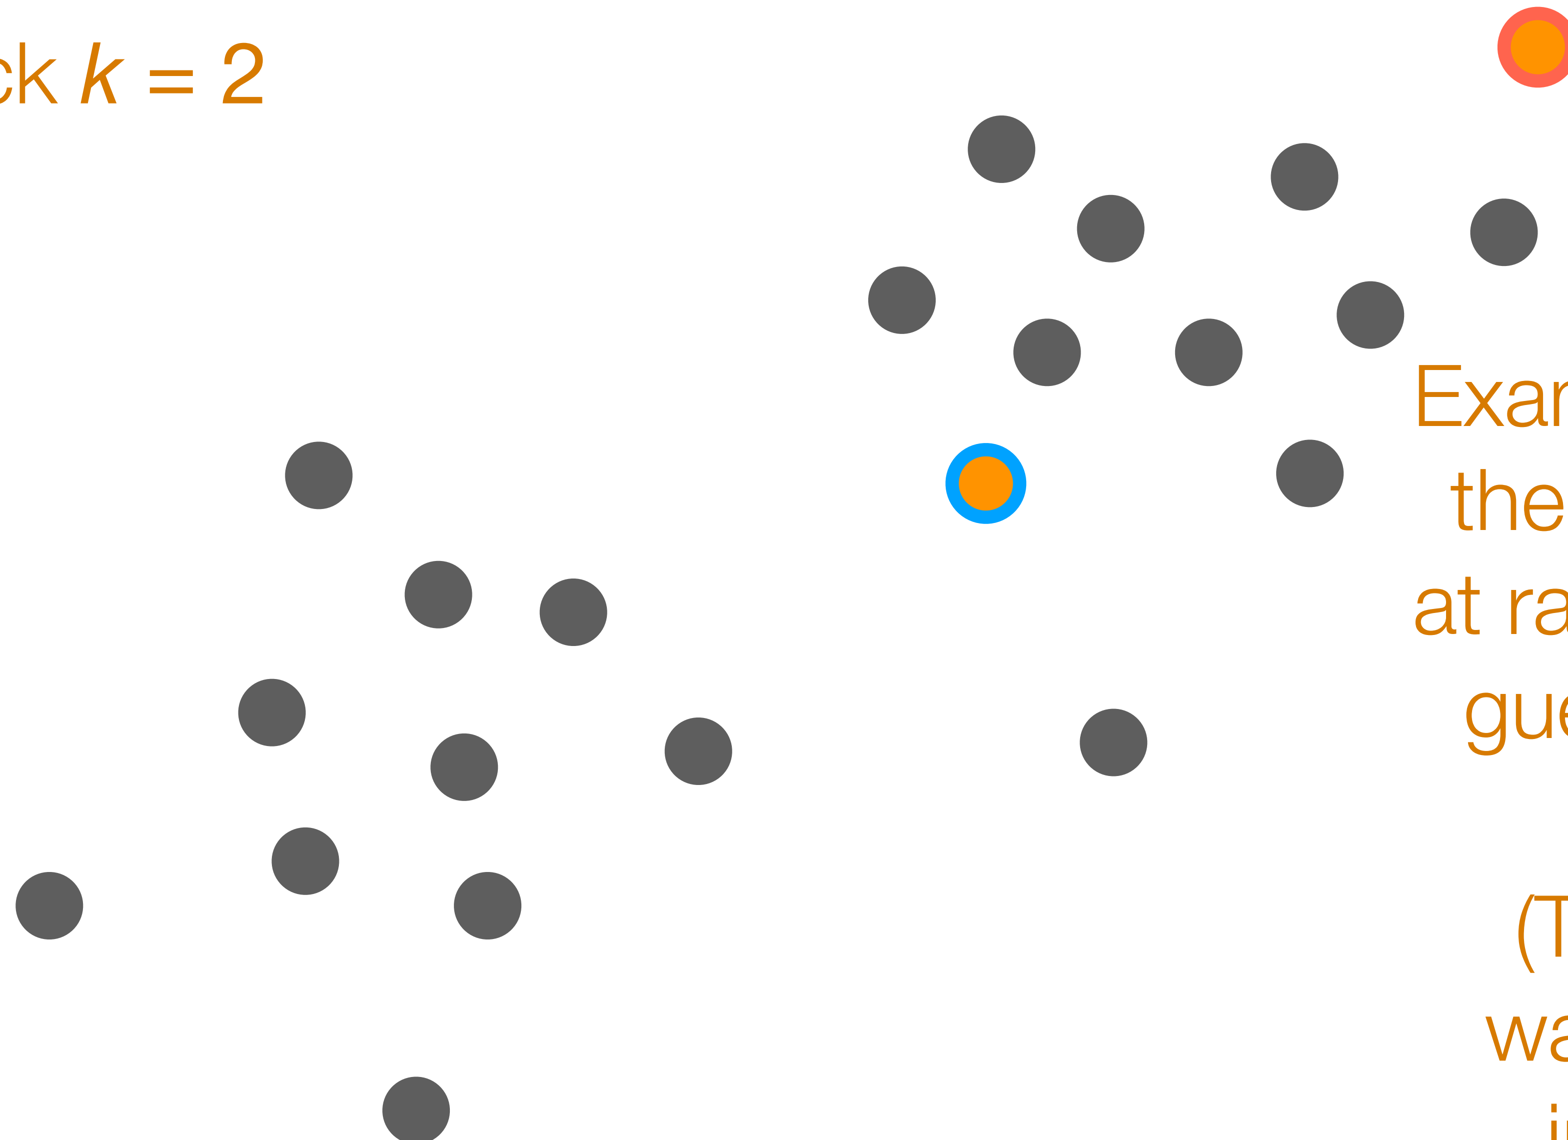


k-means

Step 0: Pick k

We'll pick k = 2

Step 1: Pick <u>guesses</u> for where cluster centers are



Example: choose k of the points uniformly at random to be initial guesses for cluster centers

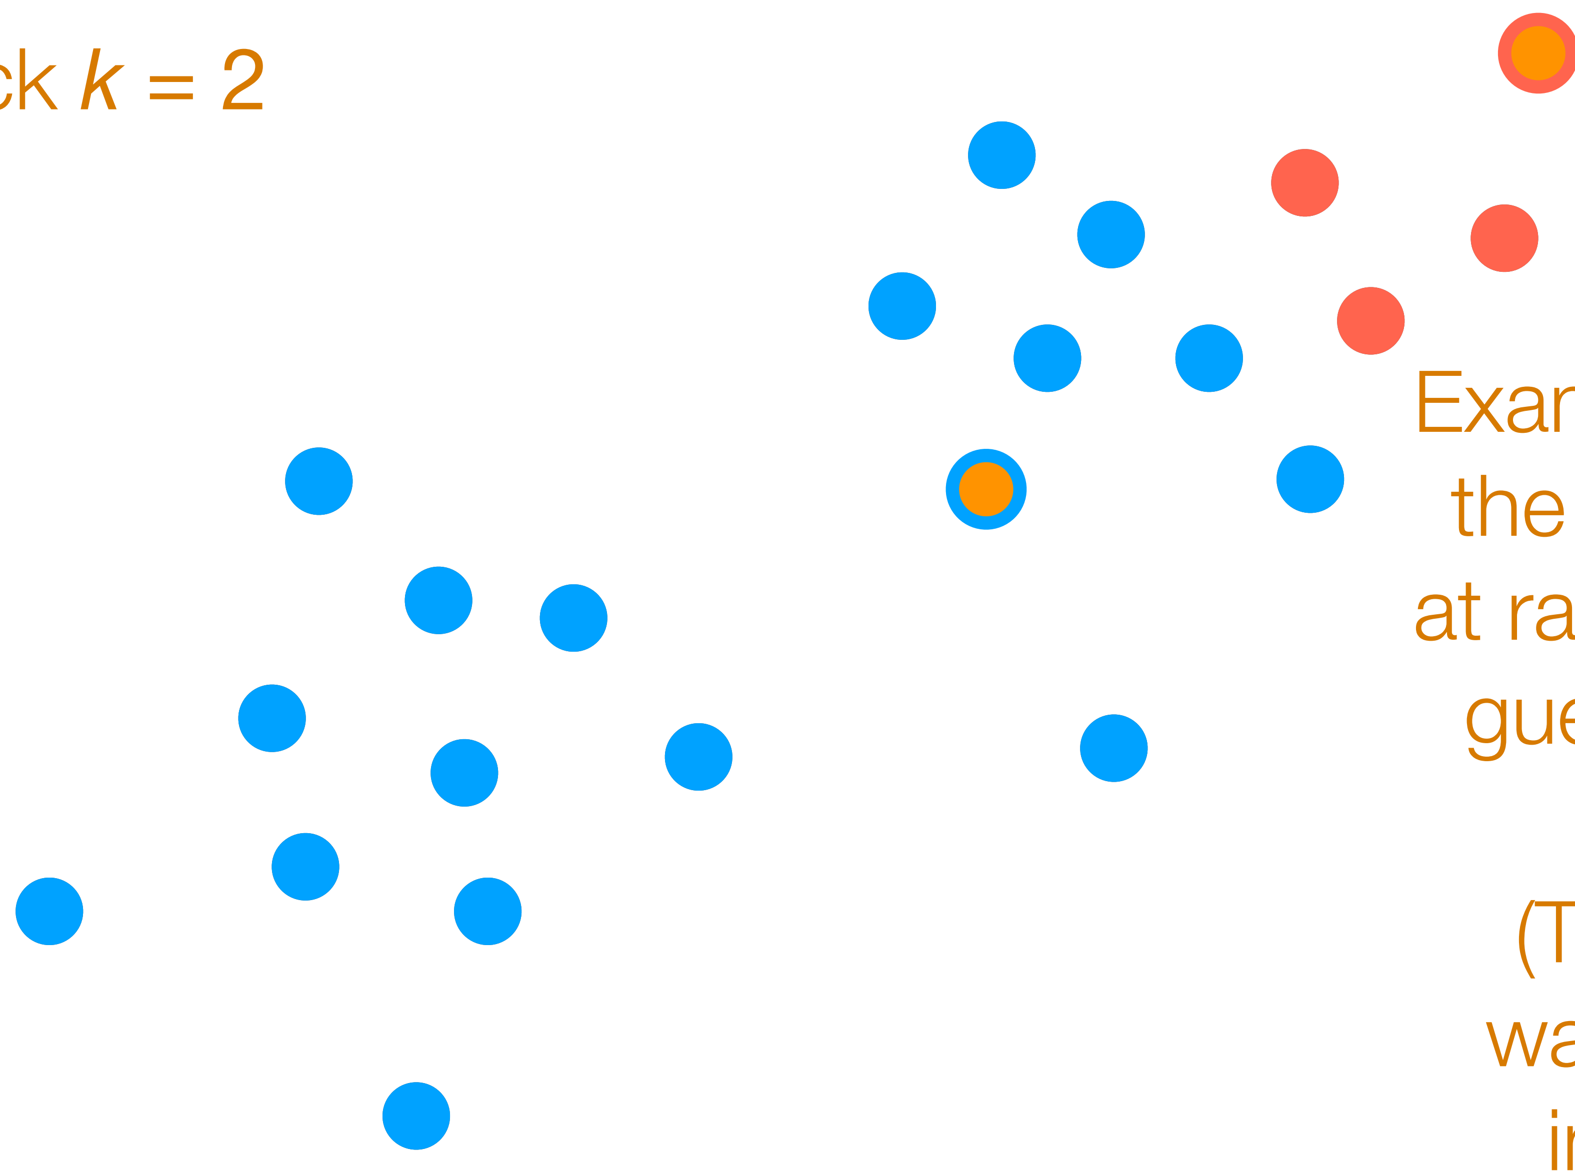
(There are many ways to make the initial guesses)

k-means

Step 1: Pick <u>guesses</u> for where cluster centers are

Step 0: Pick *k*

We'll pick $k = 2$



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

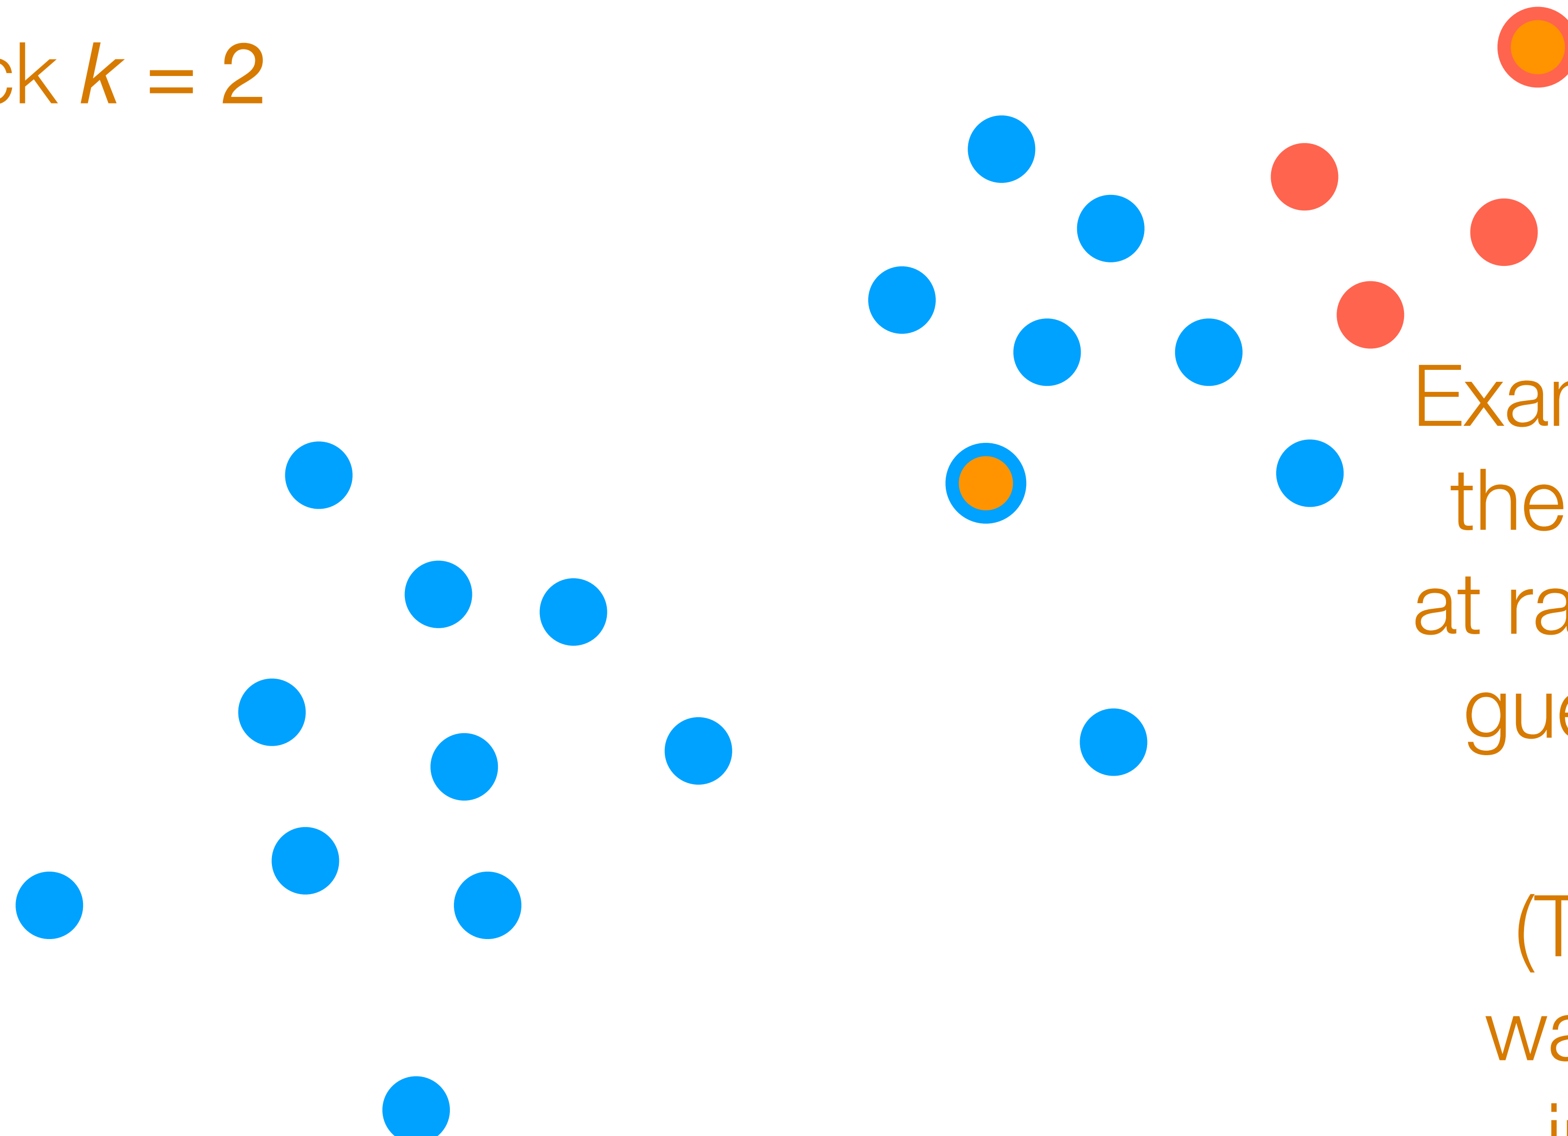
Step 2: Assign each point to belong to the closest cluster

k-means

Step 0: Pick *k*

We'll pick *k* = 2

Step 1: Pick <u>guesses</u> for where cluster centers are



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

Step 2: Assign each point to belong to the closest cluster

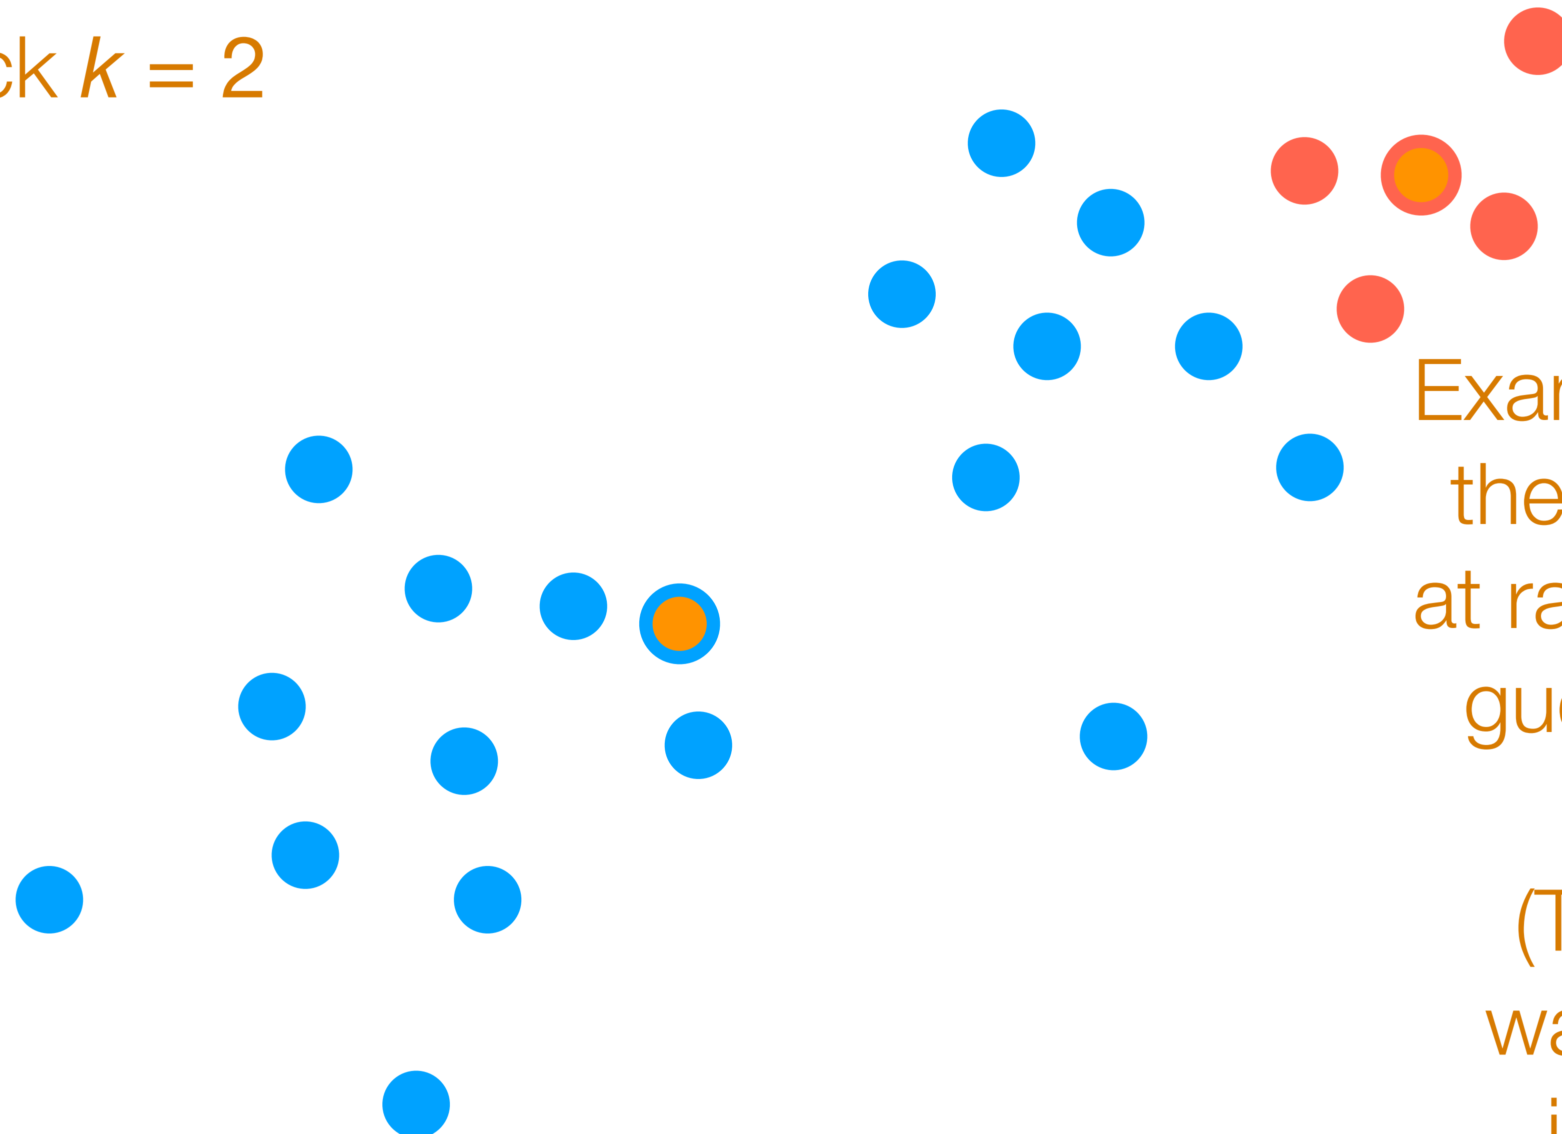
Step 3: Update cluster means (to be the center of mass per cluster)

k-means

Step 0: Pick *k*

We'll pick k = 2

Step 1: Pick <u>guesses</u> for where cluster centers are



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

Step 2: Assign each point to belong to the closest cluster

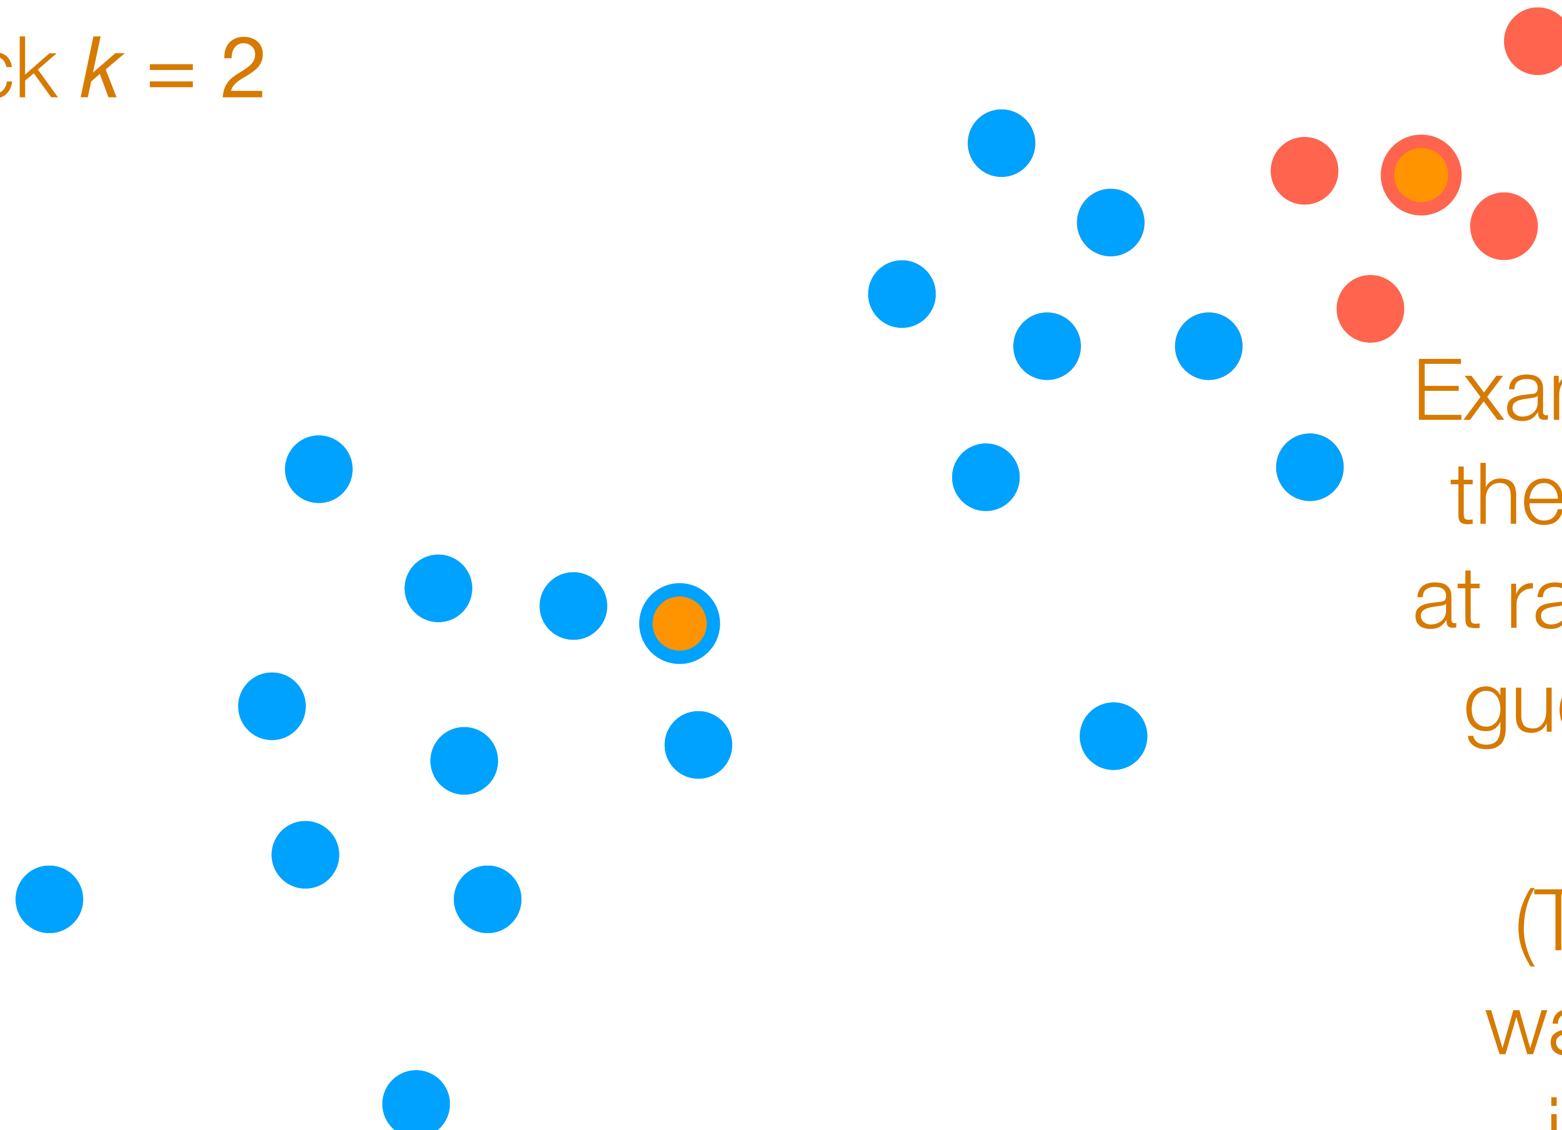
Step 3: Update cluster means (to be the center of mass per cluster)

k-means

Step 0: Pick *k*

We'll pick *k* = 2

Step 1: Pick <u>guesses</u> for where cluster centers are



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

Repeat Step 2: Assign each point to belong to the closest cluster

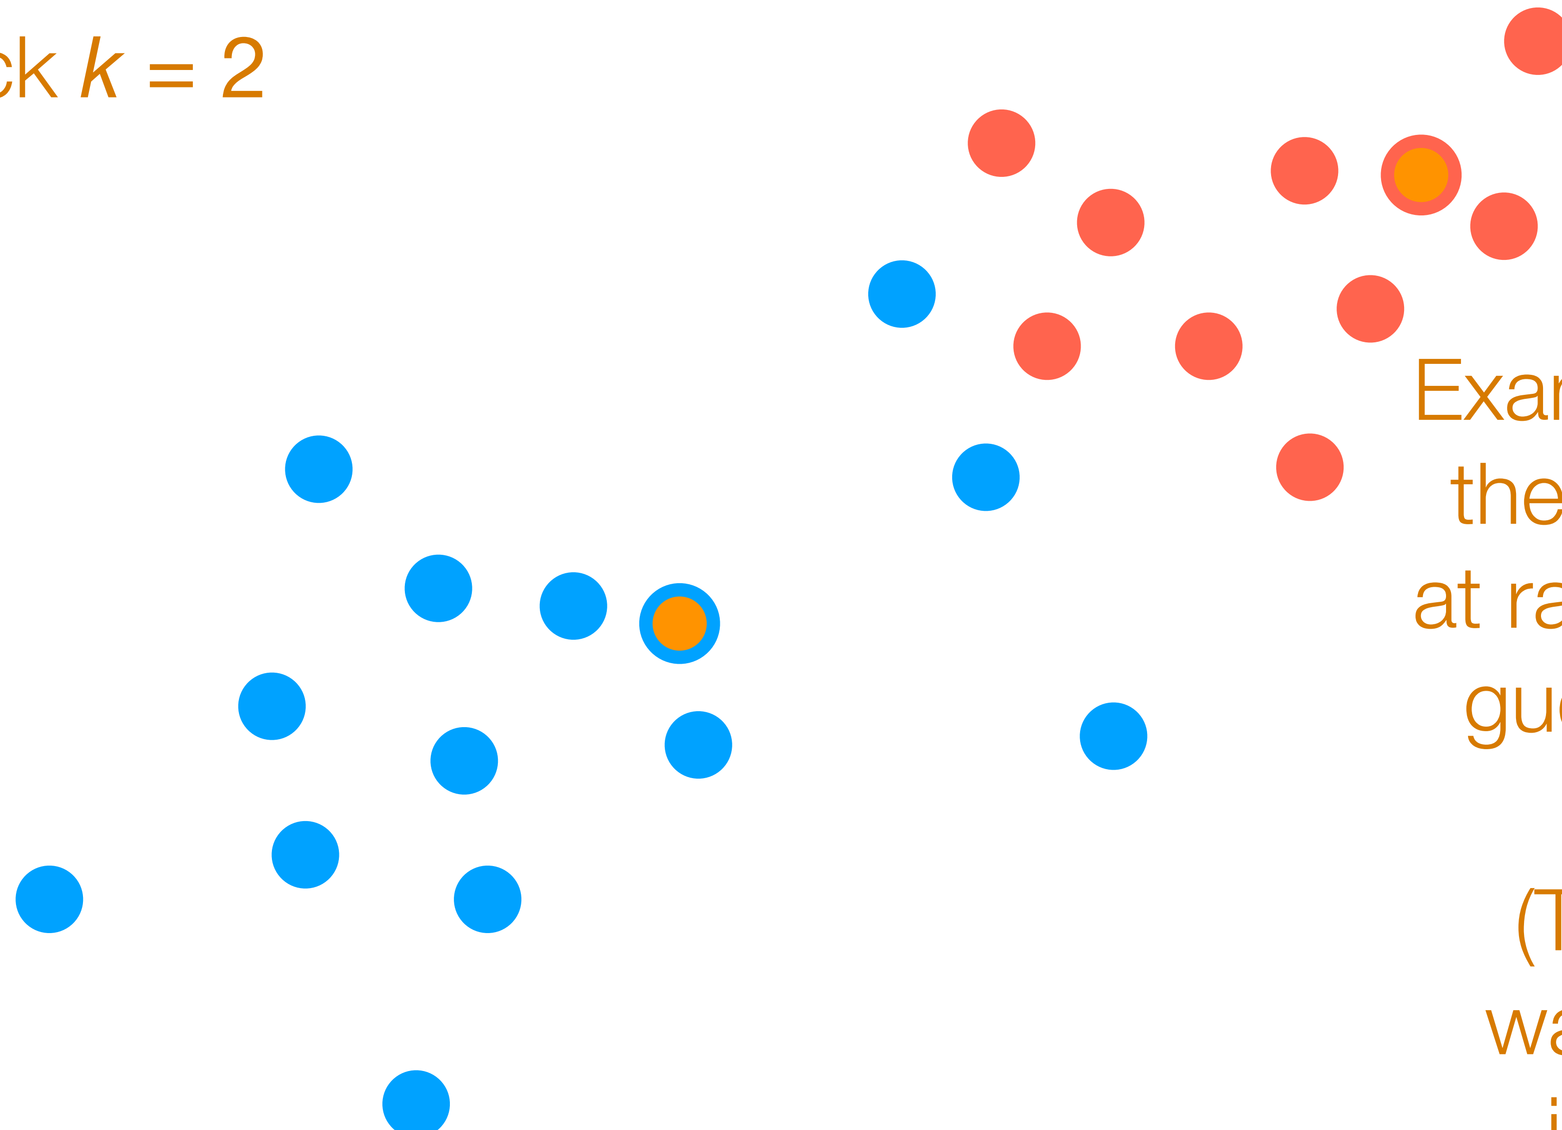
Step 3: Update cluster means (to be the center of mass per cluster)

k-means

Step 0: Pick *k*

We'll pick *k* = 2

Step 1: Pick <u>guesses</u> for where cluster centers are



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

Step 2: Assign each point to belong to the closest cluster

Repeat

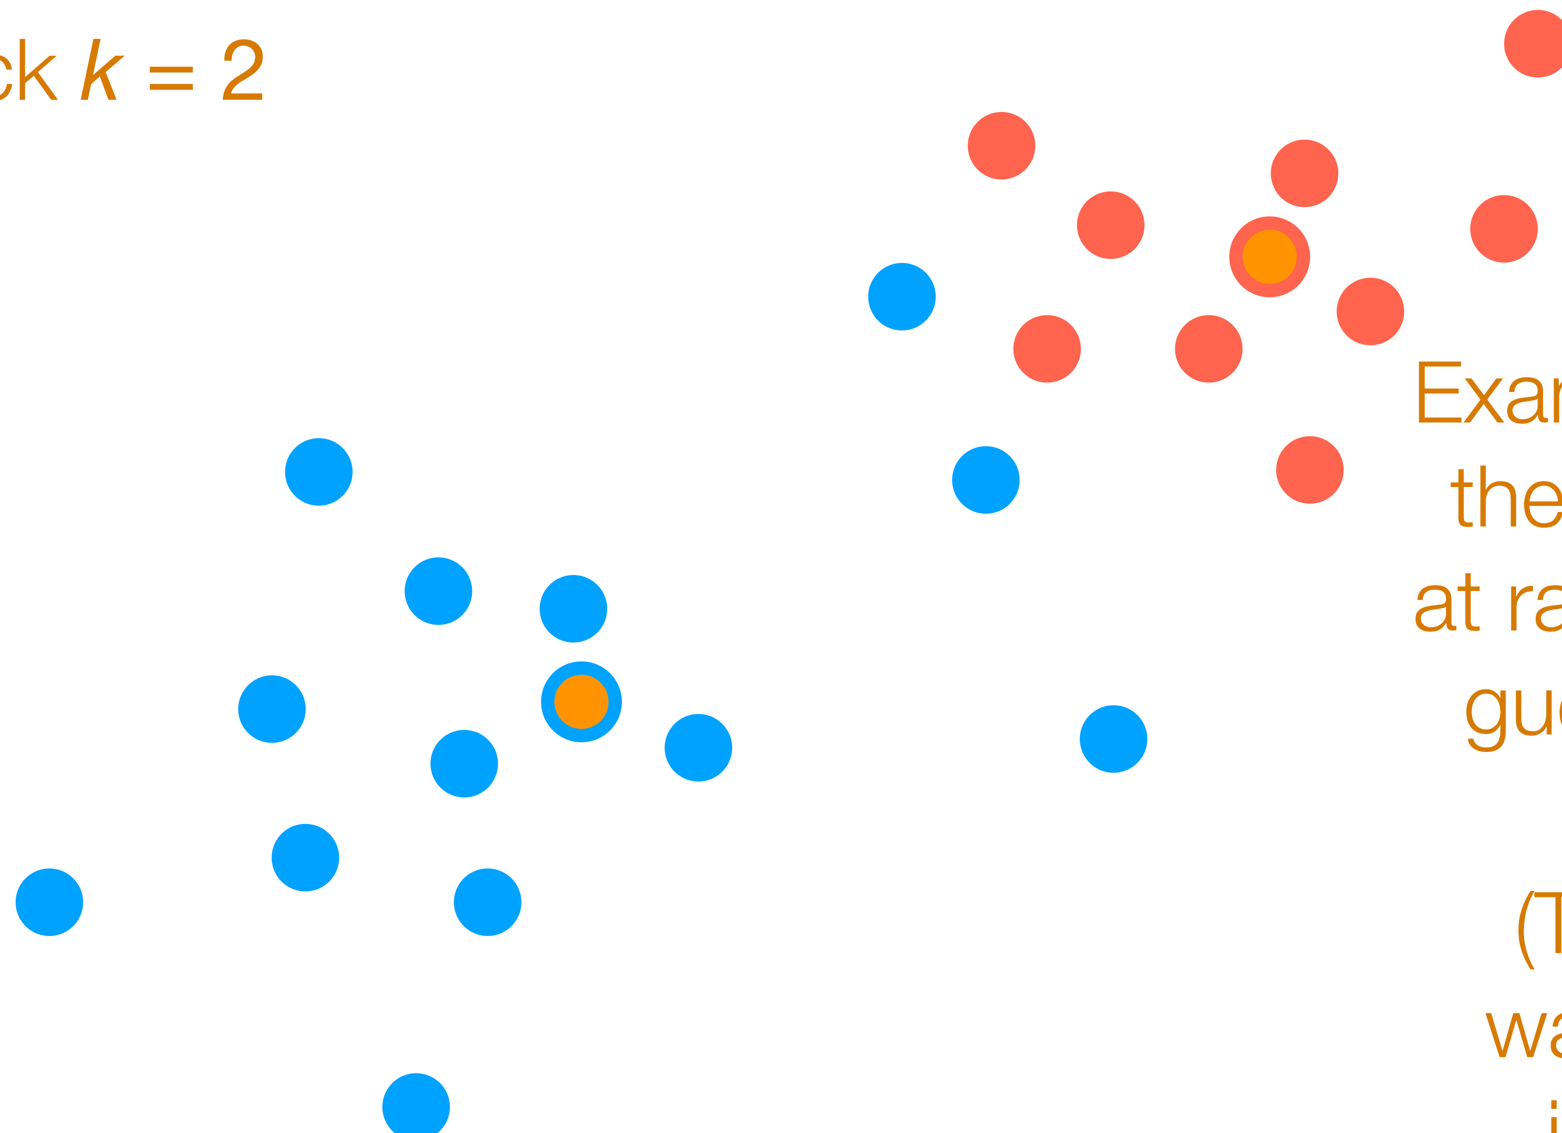
Step 3: Update cluster means (to be the center of mass per cluster)

k-means

Step 0: Pick *k*

We'll pick *k* = 2

Step 1: Pick <u>guesses</u> for where cluster centers are



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

Step 2: Assign each point to belong to the closest cluster

Repeat

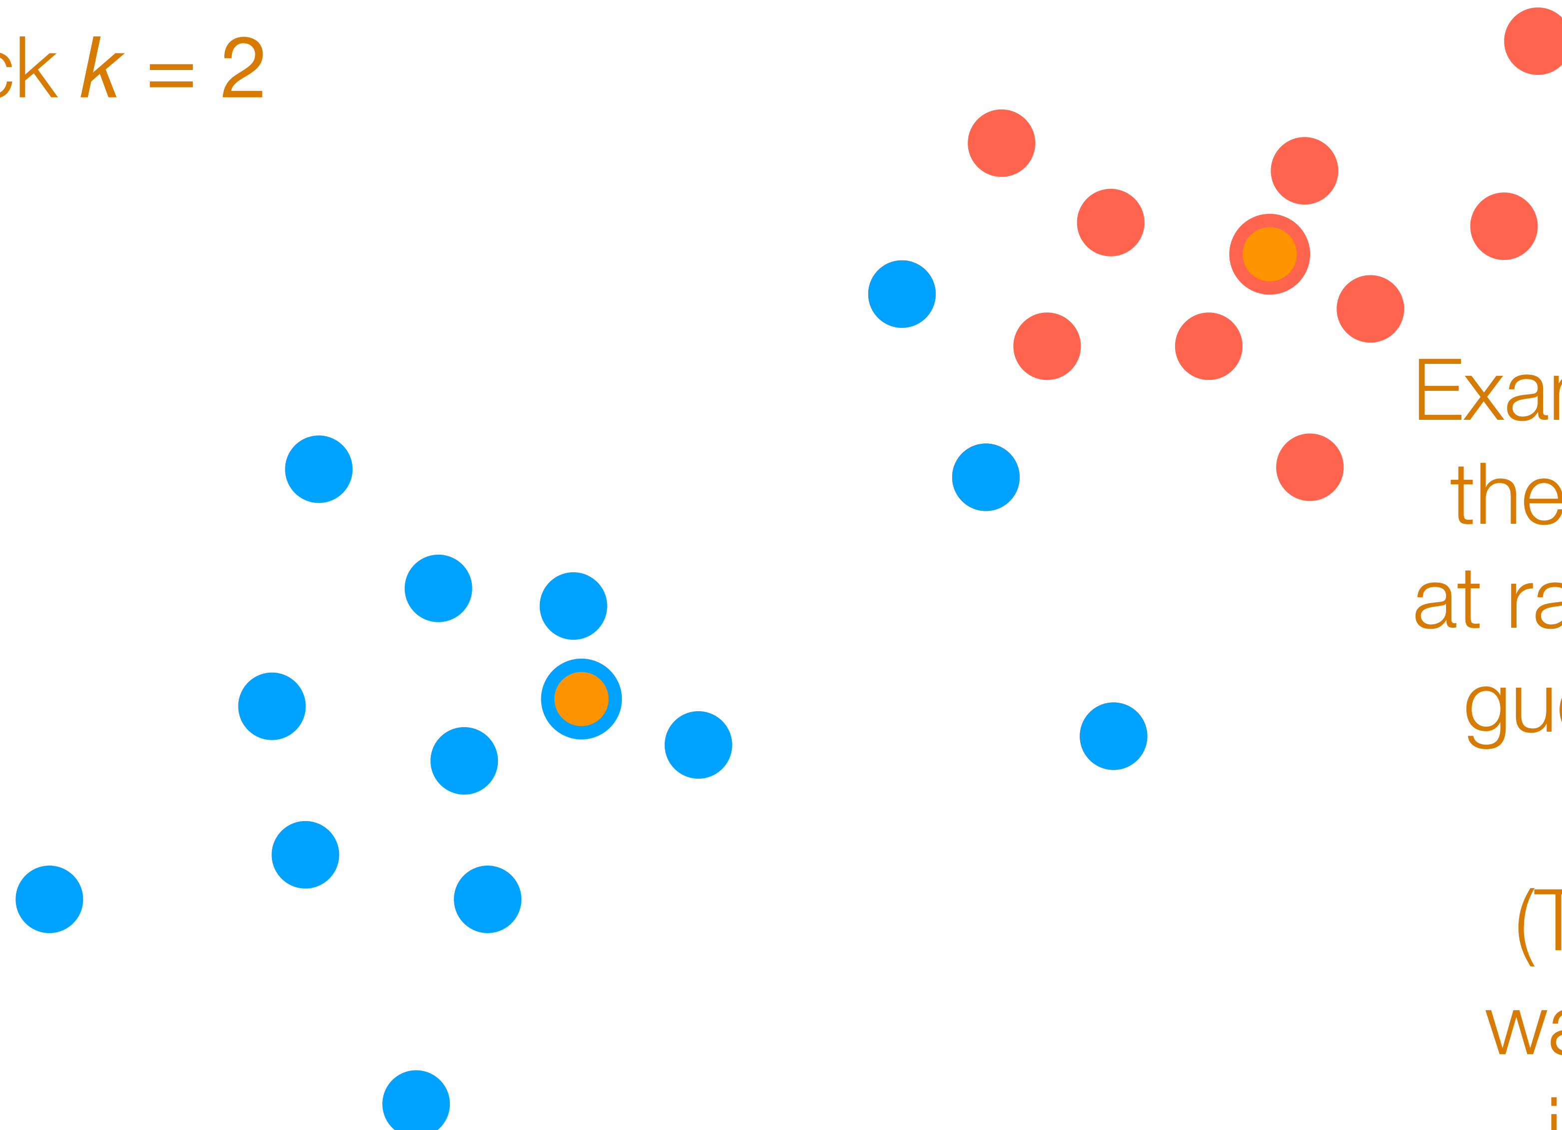
Step 3: Update cluster means (to be the center of mass per cluster)

k-means

Step 0: Pick *k*

We'll pick *k* = 2

Step 1: Pick guesses for where cluster centers are



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

Repeat Step 2: Assign each point to belong to the closest cluster

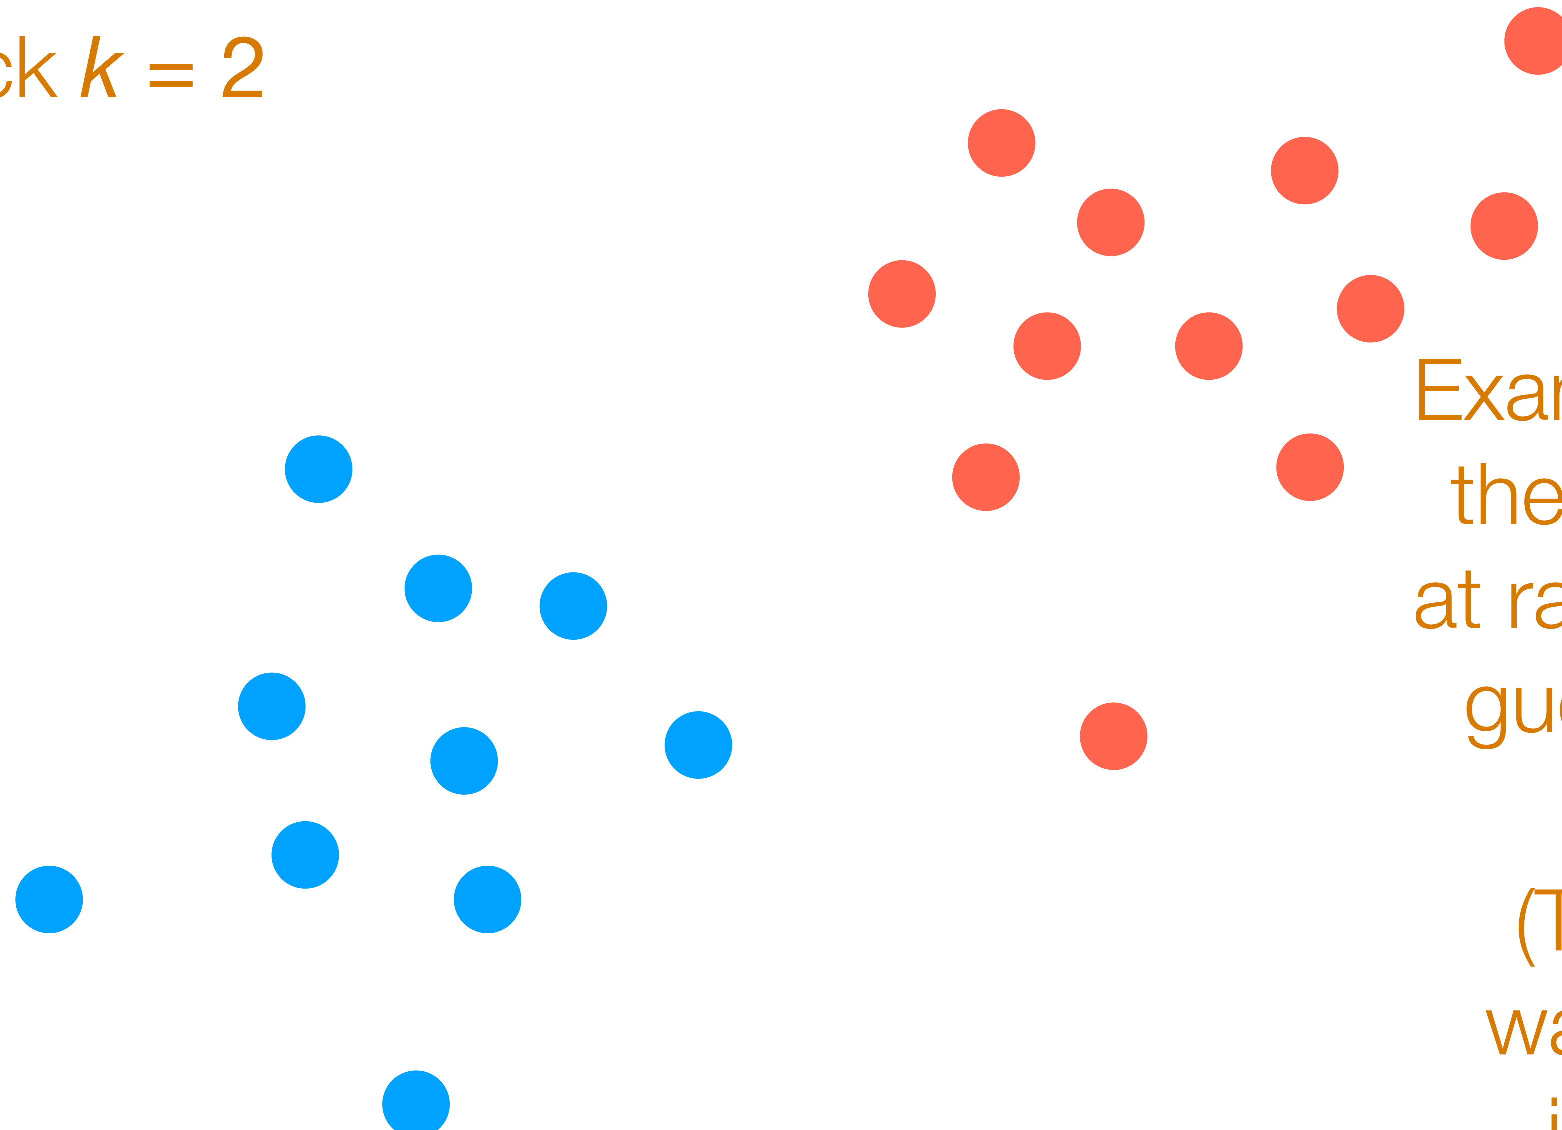
Step 3: Update cluster means (to be the center of mass per cluster)

k-means

Step 0: Pick *k*

We'll pick k = 2

Step 1: Pick guesses for where cluster centers are



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

Step 2: Assign each point to belong to the closest cluster

Repeat

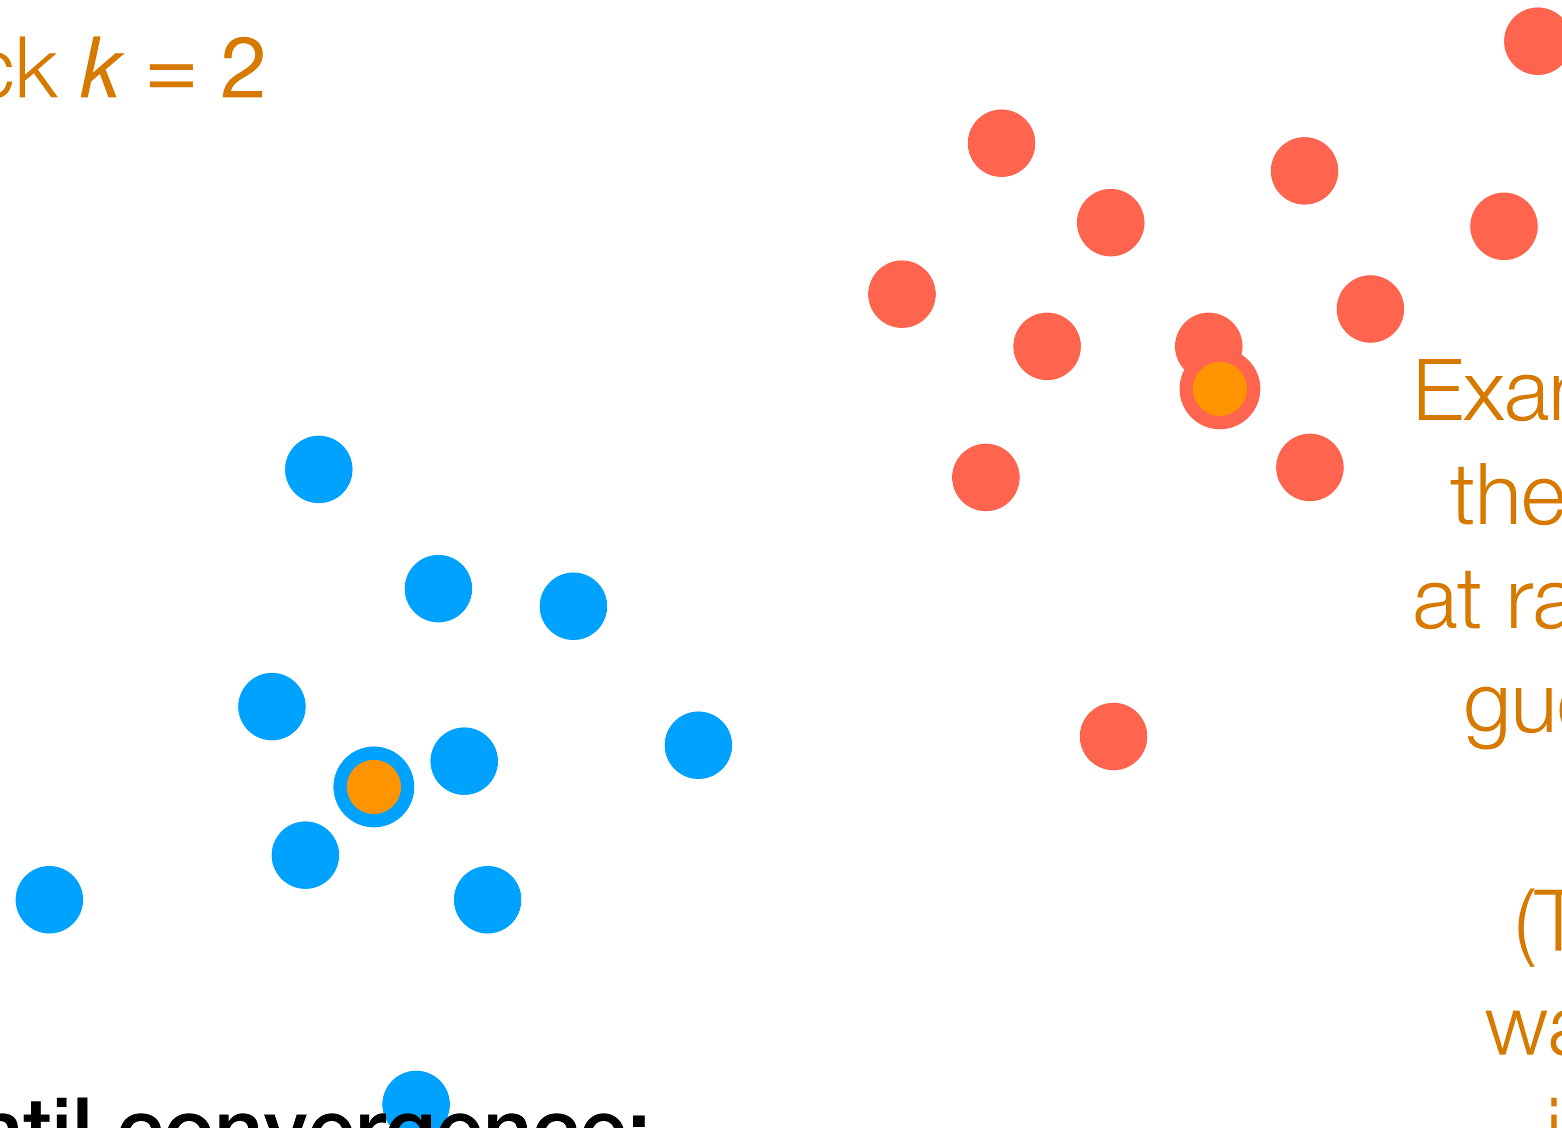
Step 3: Update cluster means (to be the center of mass per cluster)

k-means

Step 0: Pick *k*

We'll pick $k = 2$

Step 1: Pick <u>guesses</u> for where cluster centers are



Example: choose *k* of the points uniformly at random to be initial guesses for cluster centers

(There are many ways to make the initial guesses)

Repeat until convergence:

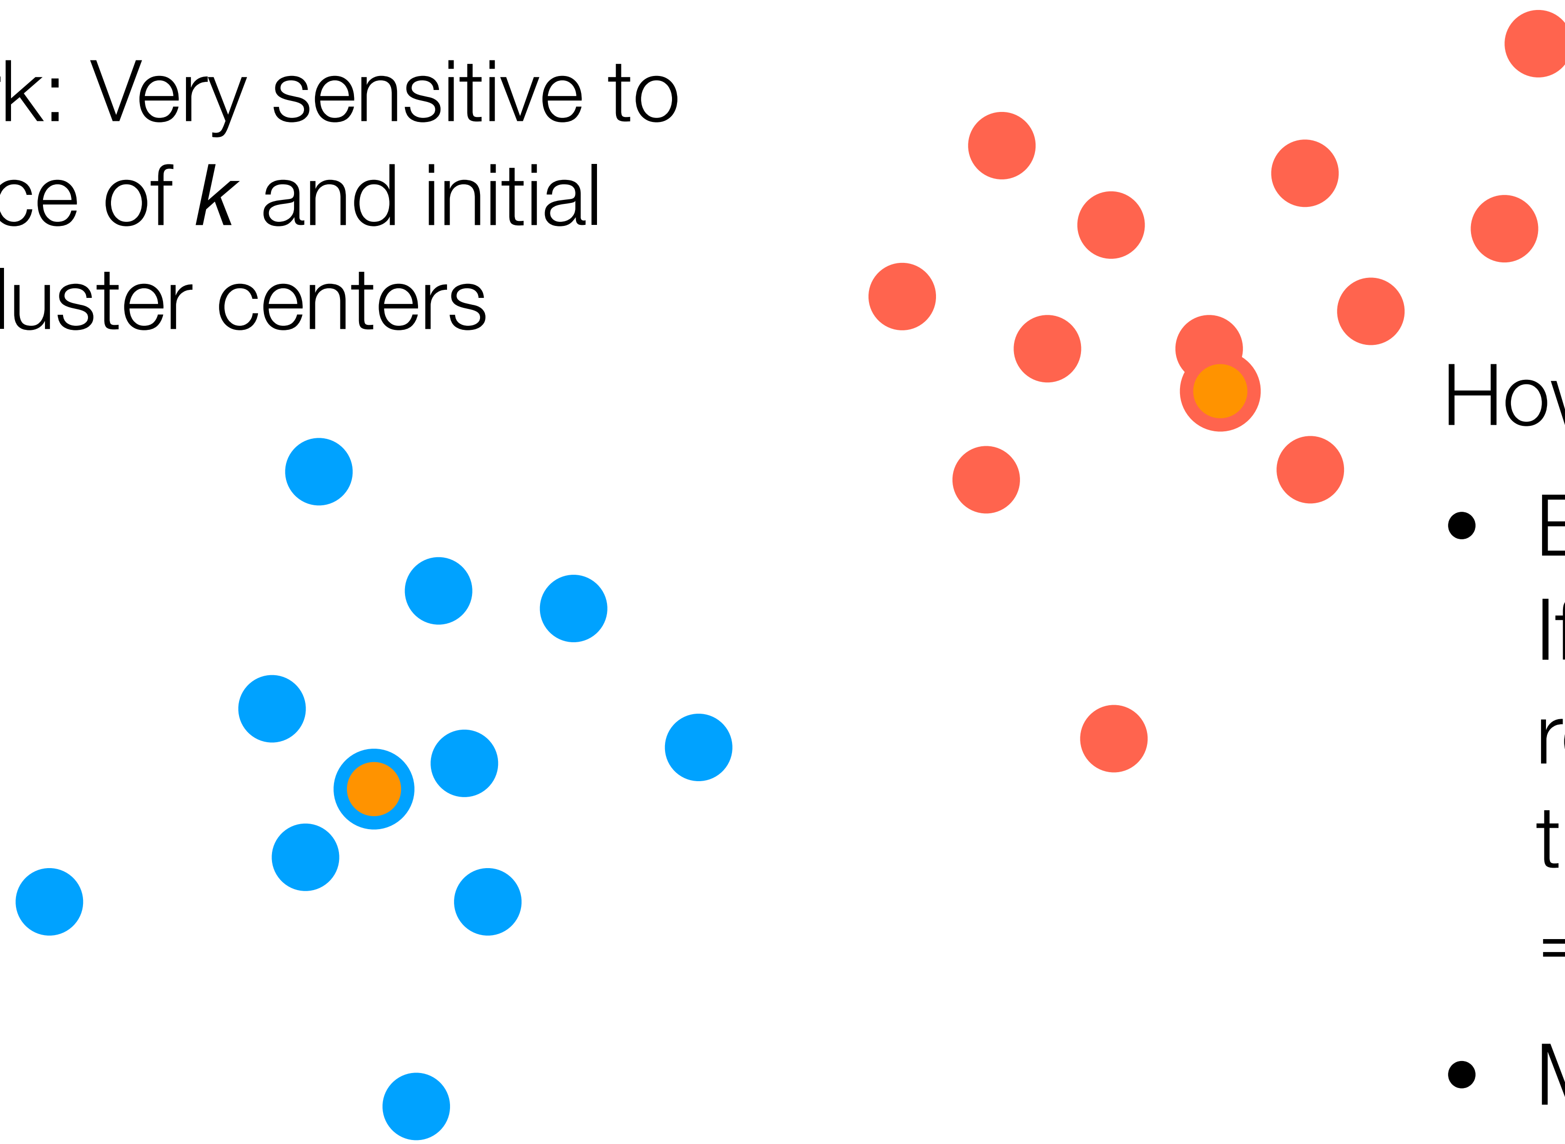
Step 2: Assign each point to belong to the closest cluster

Step 3: Update cluster means (to be the center of mass per cluster)

k-means

Final output: cluster centers, cluster assignment for every point

Remark: Very sensitive to choice of *k* and initial cluster centers



How to pick *k*?

- Basic check: If you have really, really tiny clusters $\Rightarrow$ decrease *k*
- More details later

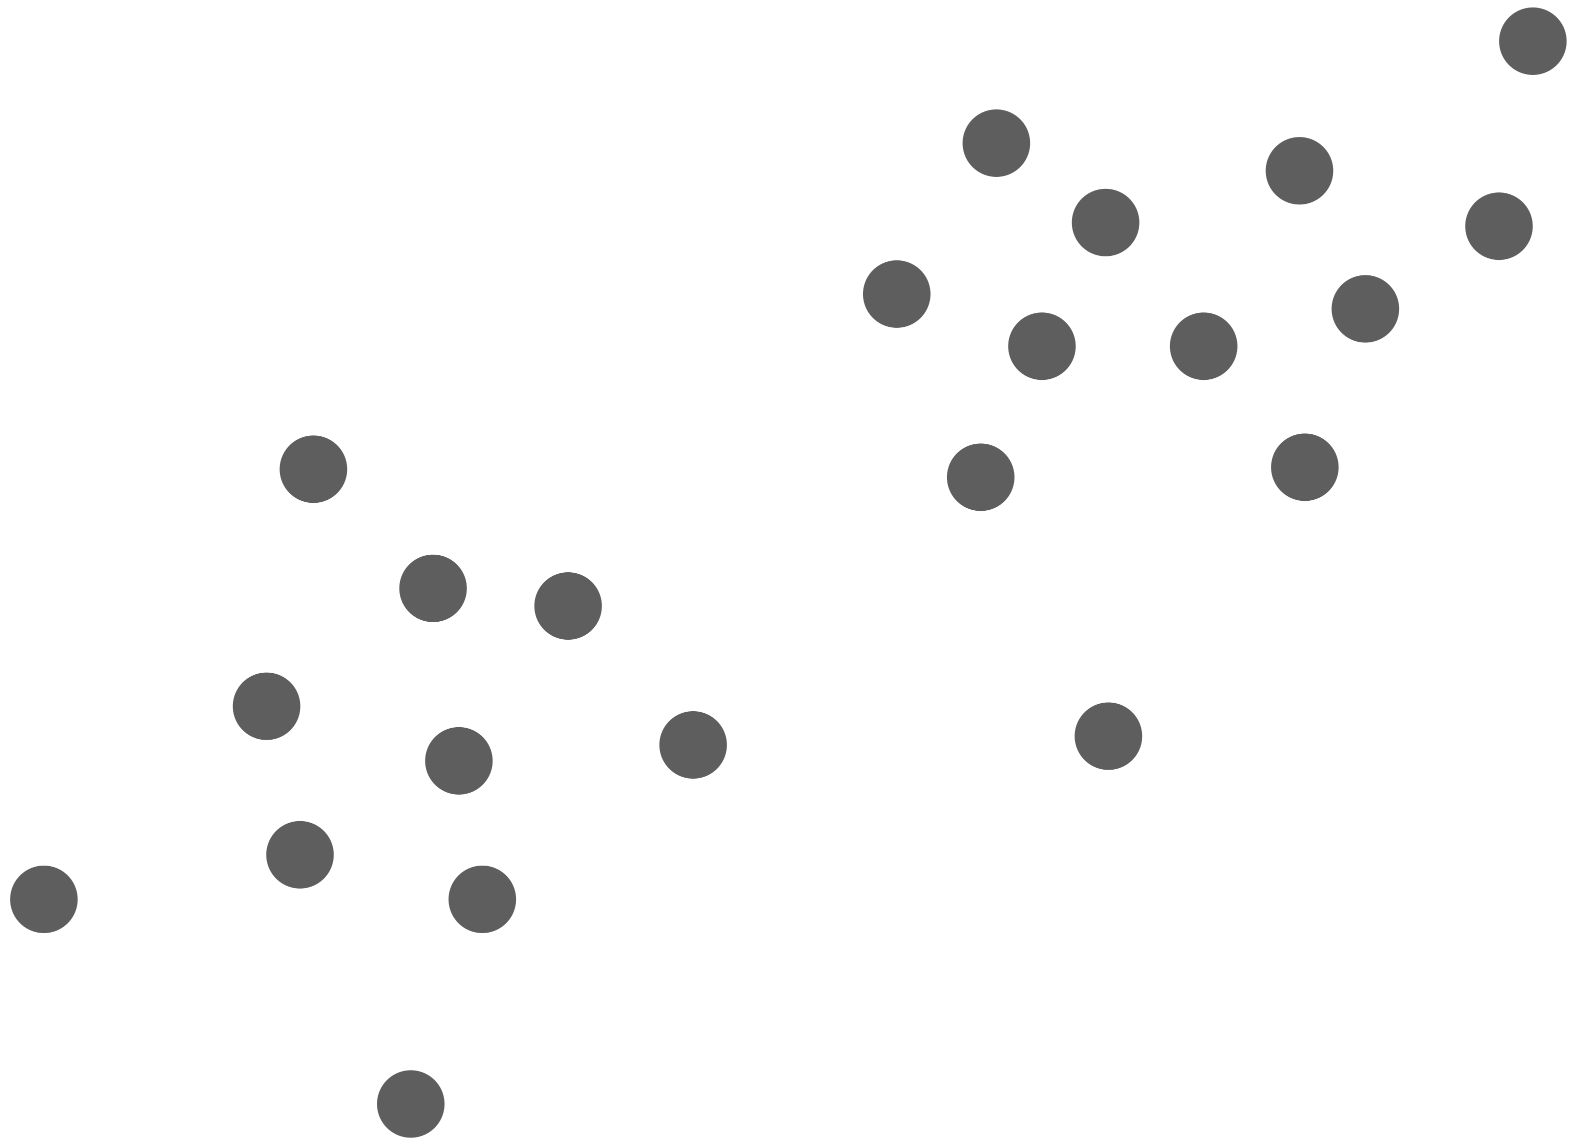
Suggested way to pick initial cluster centers: "*k*-means++" method

(rough intuition: incrementally add centers; favor adding center far away from centers chosen so far)

When does *k*-means work well?

k-means is related to a more general model, which will help us understand *k*-means

Gaussian Mixture Model (GMM)



What random process could have generated these points?

Generative Process

Think of flipping a coin

each outcome: heads or tails

Each flip doesn't depend on any of the previous flips

Generative Process

Think of flipping a coin

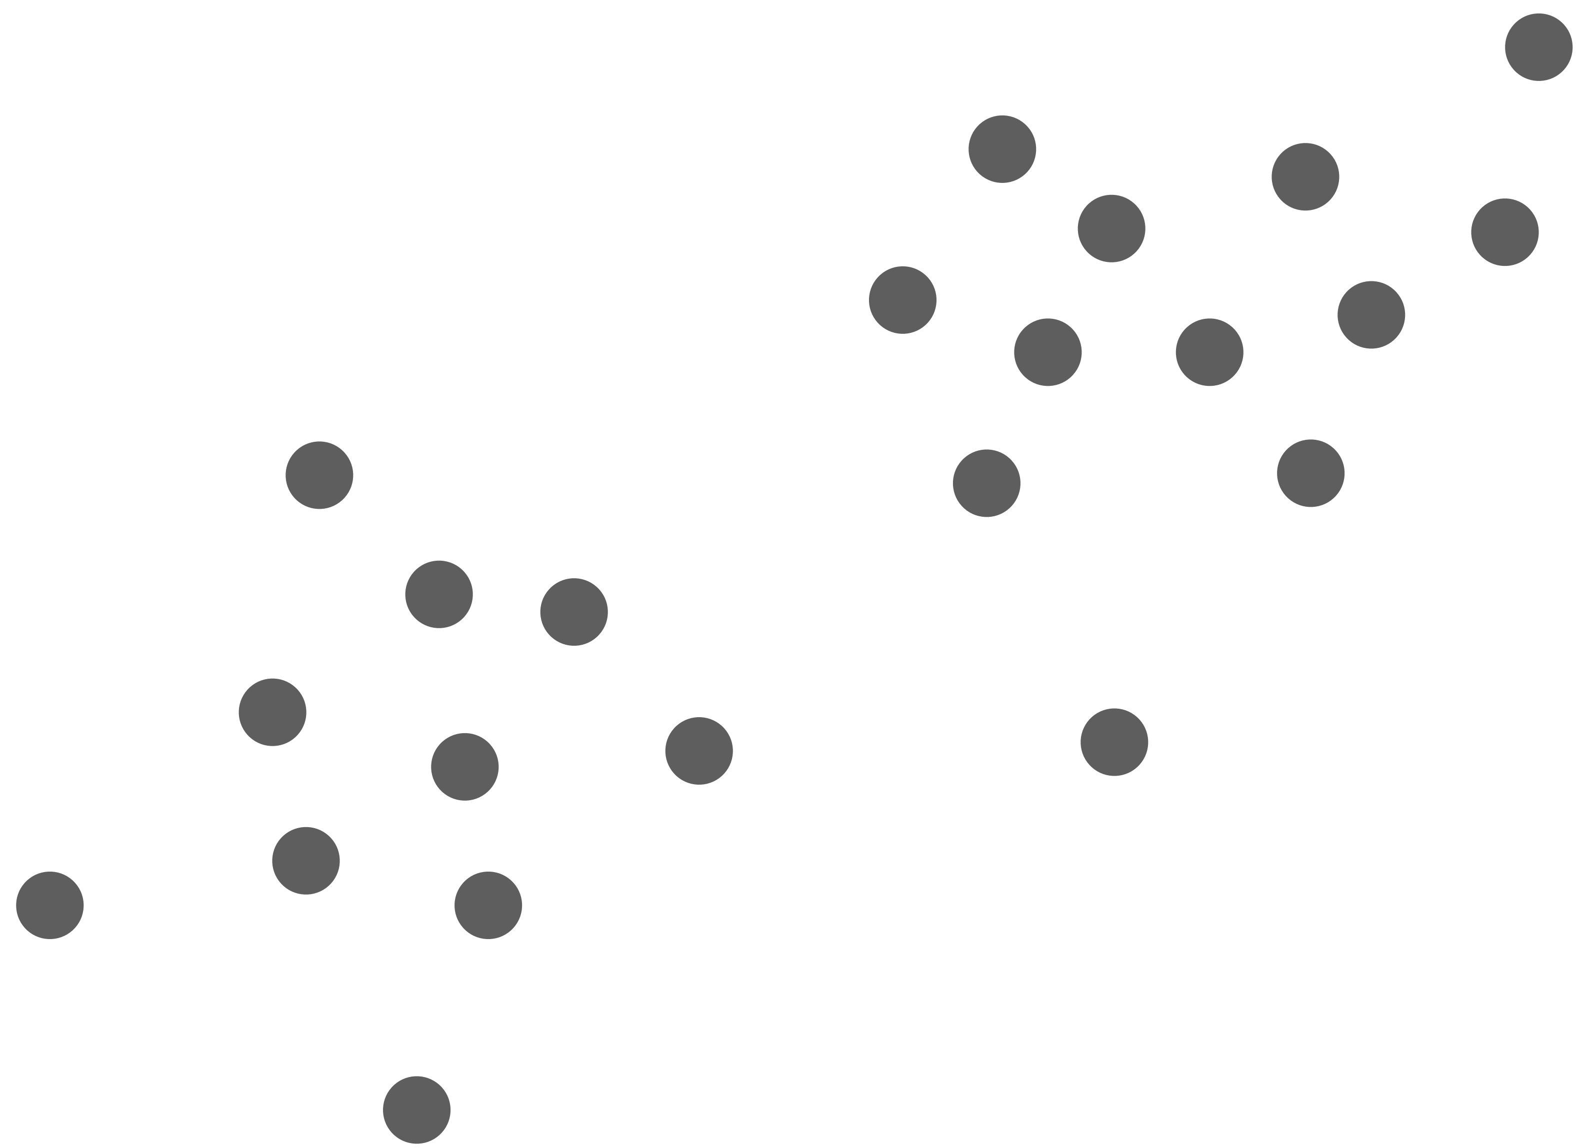
each outcome: 2D point

Each flip doesn't depend on any of the previous flips

Okay, maybe it's bizarre to think of it as a coin…

If it helps, just think of it as you pushing a button and a random 2D point appears…

Gaussian Mixture Model (GMM)



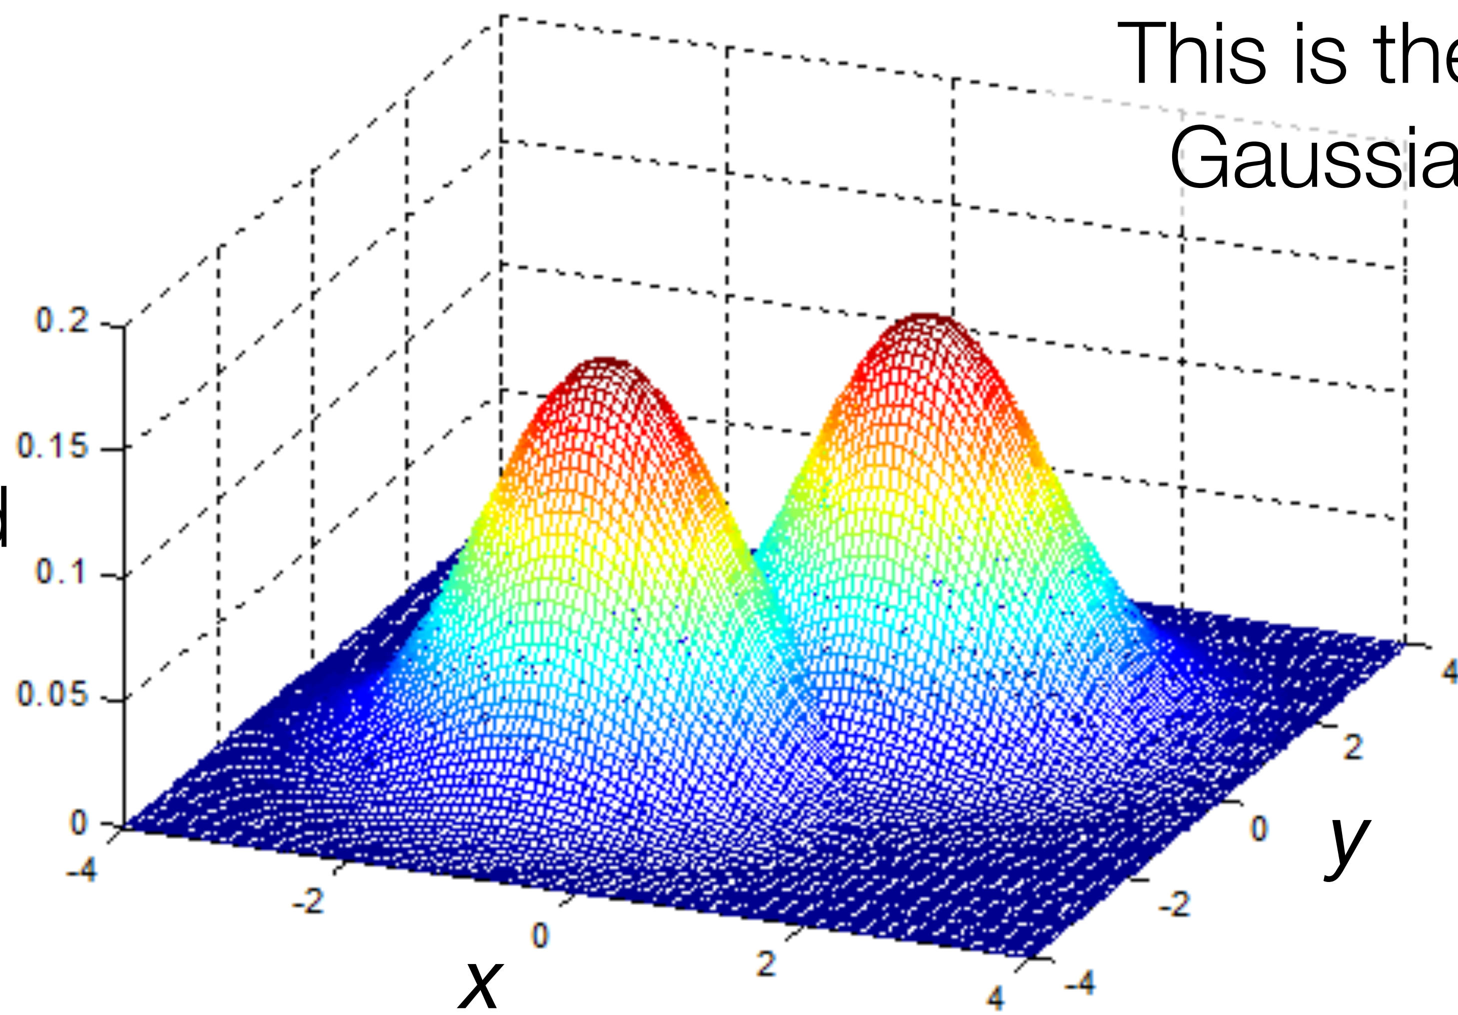
We now discuss a way to generate points in this manner

Gaussian Mixture Model (GMM)

Assume: points sampled independently from a probability distribution

This is the sum of two 2D Gaussian distributions!

how probable point generated at (x, y) is



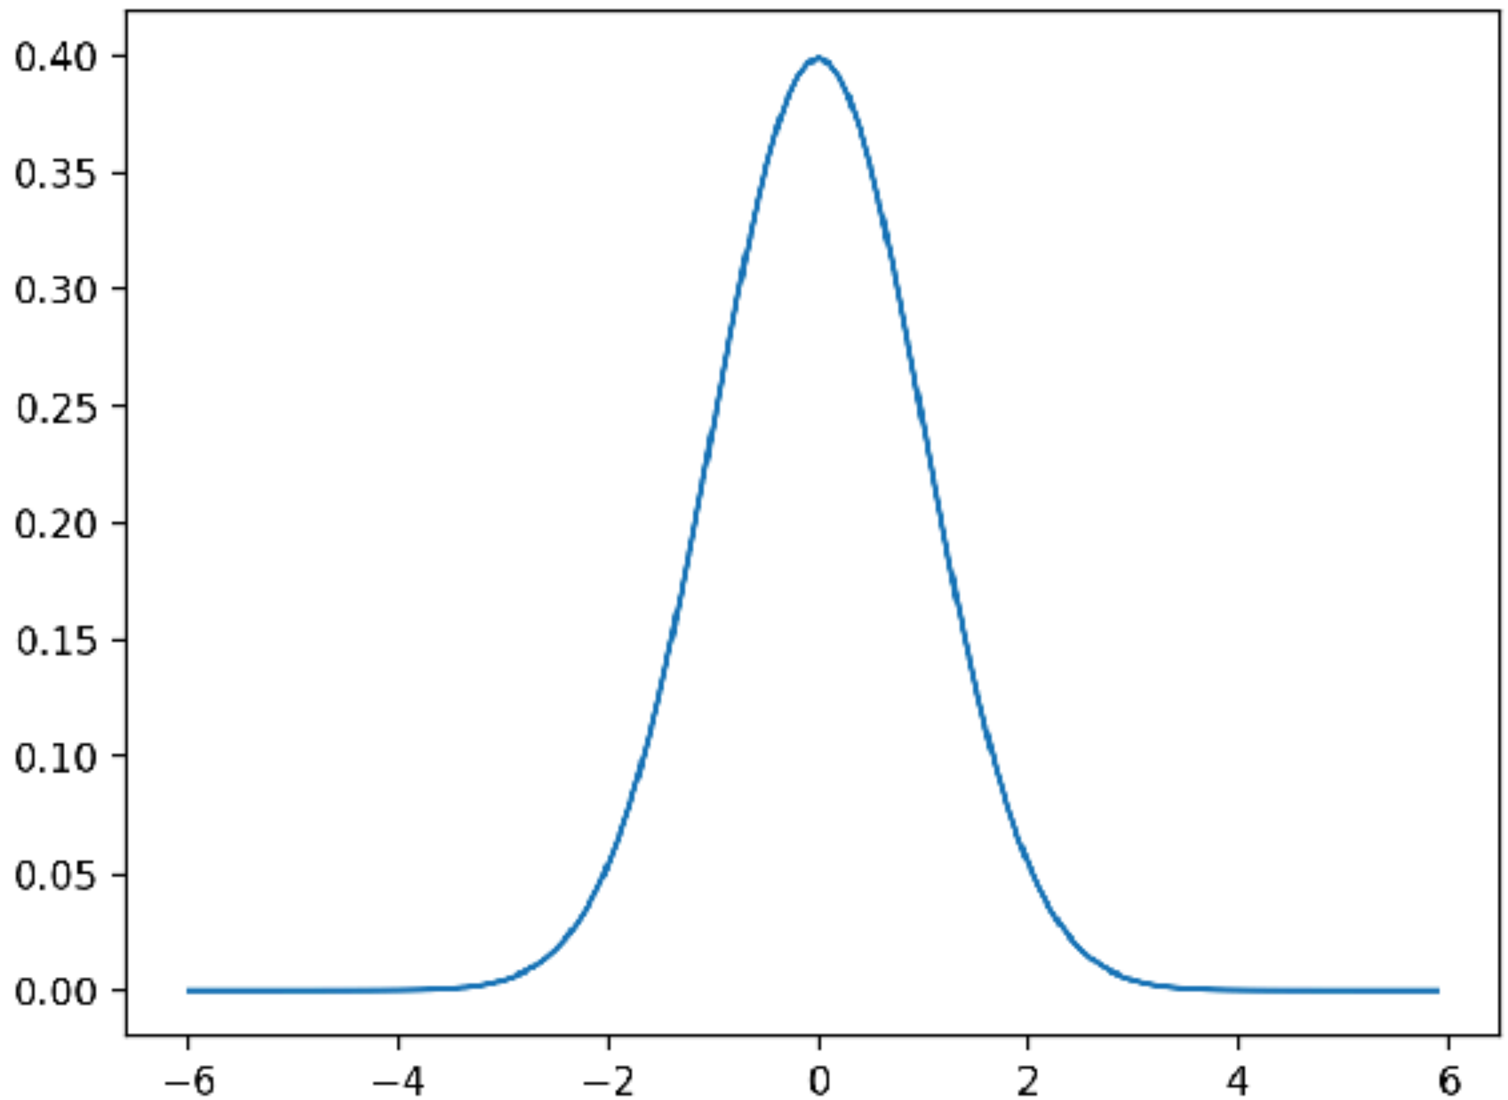
Red = more likely

Blue = less likely

Example of a 2D probability distribution

Image source: https://www.intechopen.com/source/html/17742/media/image25.png

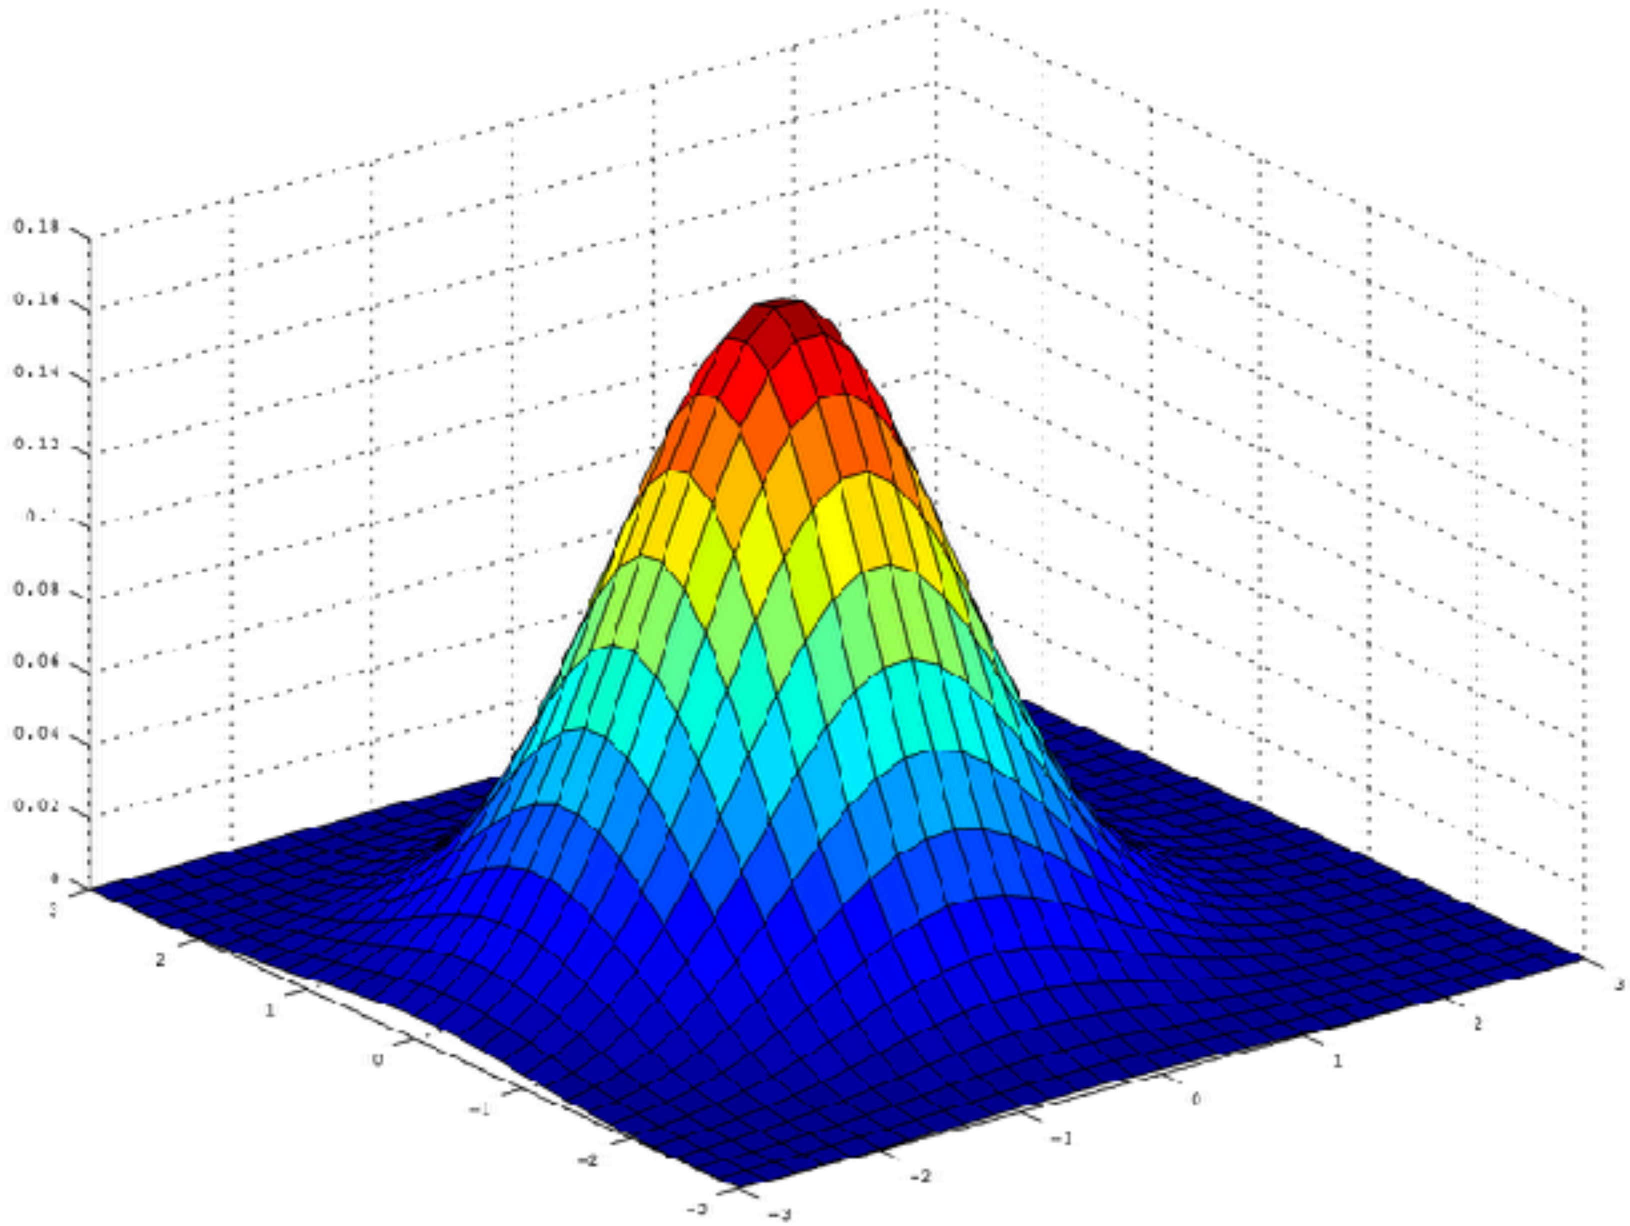
Quick Reminder: 1D Gaussian



This is a 1D Gaussian distribution

Image source: https://matthew-brett.github.io/teaching//smoothing_intro-3.hires.png

2D Gaussian



This is a 2D Gaussian distribution

Image source: https://i.stack.imgur.com/OlWce.png

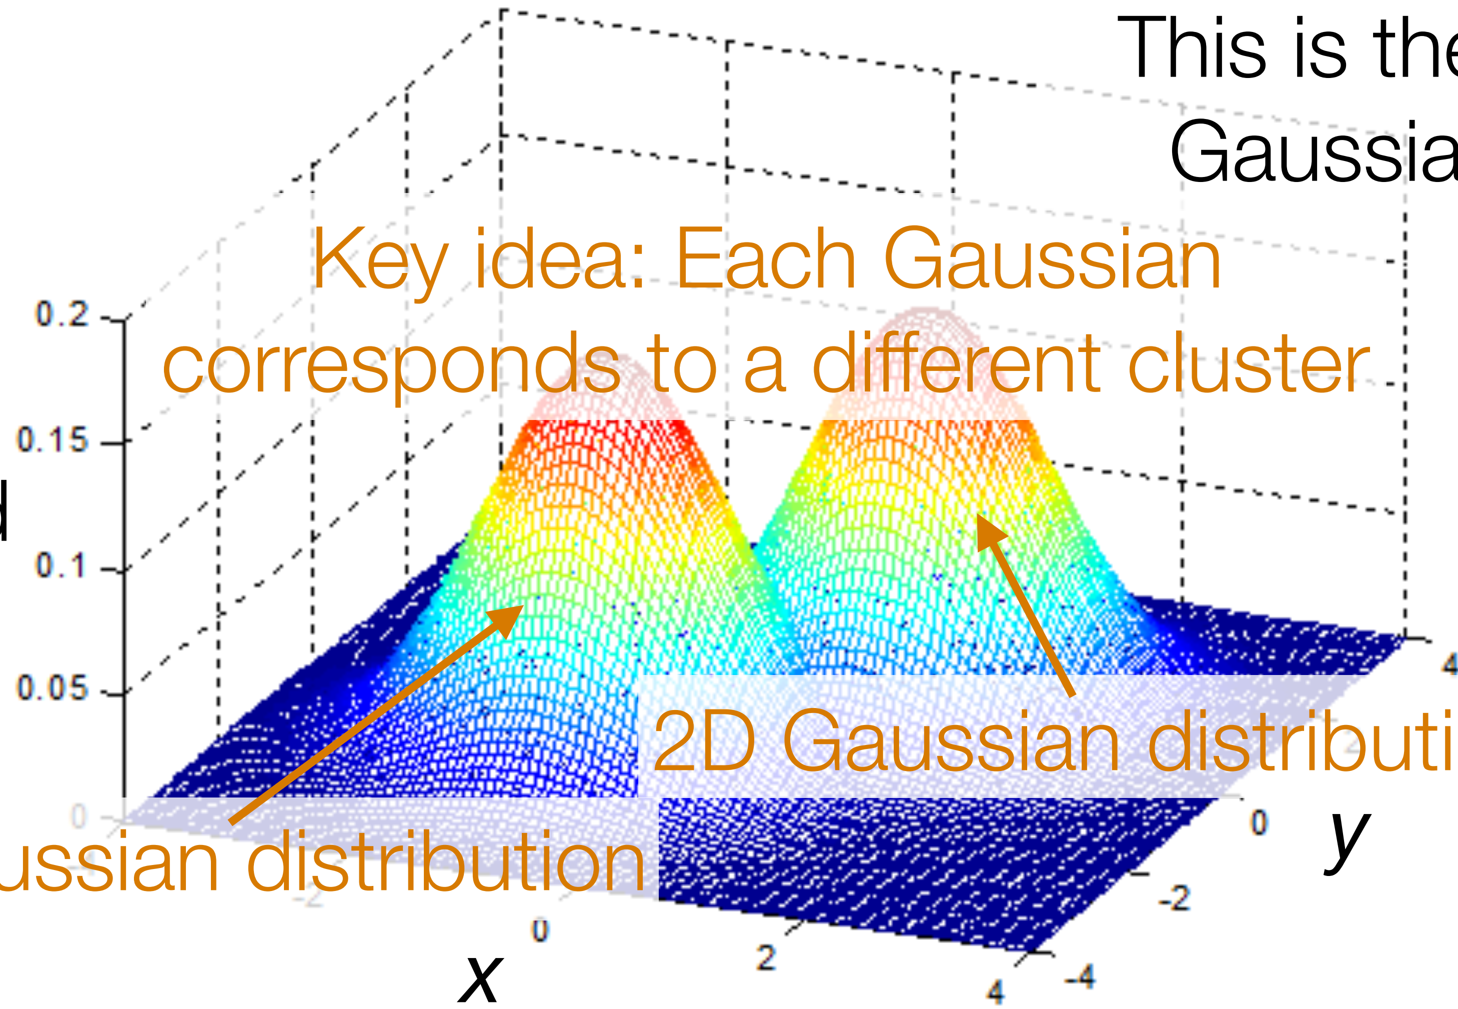
Gaussian Mixture Model (GMM)

Assume: points sampled independently from a probability distribution

This is the sum of two 2D Gaussian distributions!

Key idea: Each Gaussian corresponds to a different cluster

how probable point generated at (x, y) is



Red = more likely

Blue = less likely

2D Gaussian distribution

2D Gaussian distribution

y

x

Example of a 2D probability distribution

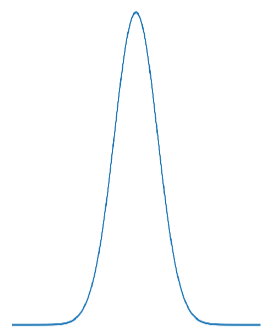
Image source: https://www.intechopen.com/source/html/17742/media/image25.png

Gaussian Mixture Model (GMM)

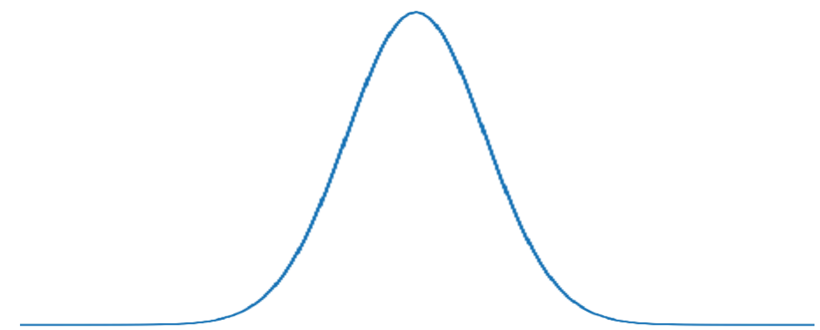
- For a fixed value *k* and dimension *d*, a GMM is the sum of *k* *d*-dimensional Gaussian distributions so that the overall probability distribution looks like *k* mountains (We've been looking at *d* = 2)
  - Each mountain corresponds to a different cluster
  - Different mountains can have different peak heights
  - One missing thing we haven't discussed yet: different mountains can have different shapes

2D Gaussian Shape

In 1D, you can have a skinny Gaussian or a wide Gaussian



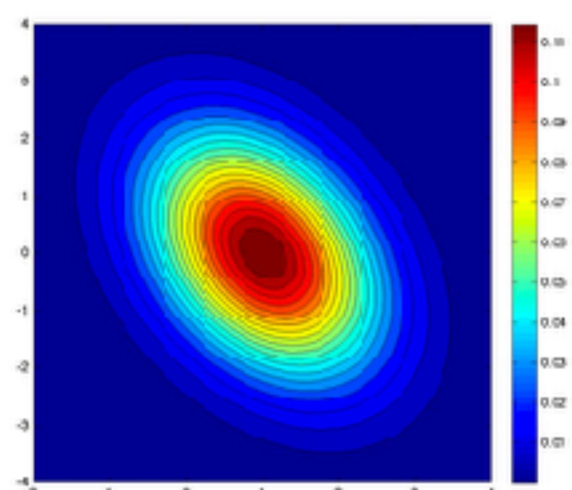
Less uncertainty



More uncertainty

In 2D, you can more generally have ellipse-shaped Gaussians

Ellipse enables encoding relationship between variables



Can't have arbitrary shapes

Top-down view of an example 2D Gaussian distribution

Image source: https://www.cs.colorado.edu/~mozer/Teaching/syllabi/ProbabilisticModels2013/homework/assign5/a52dgauss.jpg

Gaussian Mixture Model (GMM)

- For a fixed value *k* and dimension *d*, a GMM is the sum of *k* *d*-dimensional Gaussian distributions so that the overall probability distribution looks like *k* mountains (We've been looking at *d* = 2)
  - Each mountain corresponds to a different cluster
  - Different mountains can have different peak heights
  - Different mountains can have different ellipse shapes (captures "covariance" information)

Example: 1D GMM with 2 Clusters

Cluster 1

Probability of generating a point from cluster 1 = 0.5

Gaussian mean = –5

Gaussian std dev = 1

Cluster 2

Probability of generating a point from cluster 2 = 0.5

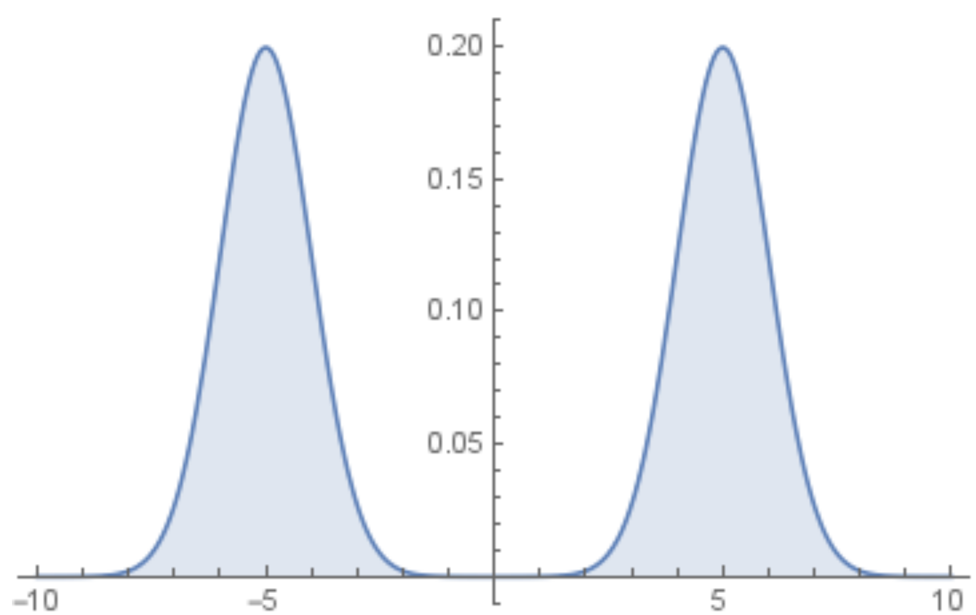
Gaussian mean = 5

Gaussian std dev = 1

What do you think this looks like?

Example: 1D GMM with 2 Clusters

Cluster 1	Cluster 2
Probability of generating a point from cluster 1 = 0.5	Probability of generating a point from cluster 2 = 0.5
Gaussian mean = –5	Gaussian mean = 5
Gaussian std dev = 1	Gaussian std dev = 1



Example: 1D GMM with 2 Clusters

Cluster 1

Probability of generating a point from cluster 1 = **0.7**

Gaussian mean = –5

Gaussian std dev = 1

Cluster 2

Probability of generating a point from cluster 2 = **0.3**

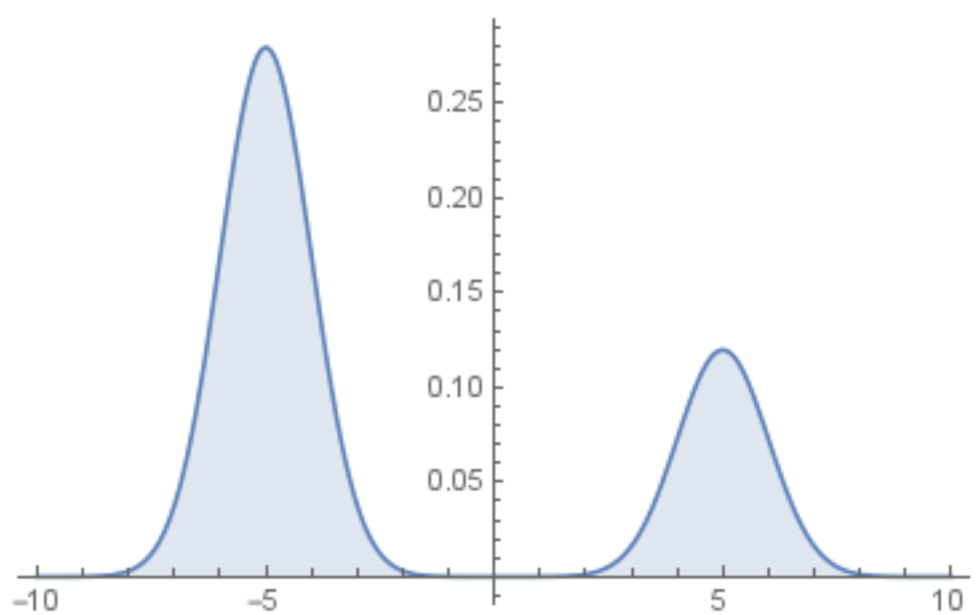
Gaussian mean = 5

Gaussian std dev = 1

What do you think this looks like?

Example: 1D GMM with 2 Clusters

Cluster 1	Cluster 2
Probability of generating a point from cluster 1 = 0.7	Probability of generating a point from cluster 2 = 0.3
Gaussian mean = –5	Gaussian mean = 5
Gaussian std dev = 1	Gaussian std dev = 1



Example: 1D GMM with 2 Clusters

Cluster 1

Probability of generating a point from cluster 1 = 0.7

Gaussian mean = –5

Gaussian std dev = 1

Cluster 2

Probability of generating a point from cluster 2 = 0.3

Gaussian mean = 5

Gaussian std dev = 1

How to generate 1D points from this GMM:

1. Flip biased coin (with probability of heads 0.7)
2. If heads: sample 1 point from Gaussian mean -5, std dev 1

   If tails: sample 1 point from Gaussian mean 5, std dev 1

Example: 1D GMM with 2 Clusters

Cluster 1

Probability of generating a point from cluster 1 = π_1

Gaussian mean = μ_1

Gaussian std dev = σ_1

Cluster 2

Probability of generating a point from cluster 2 = π_2

Gaussian mean = μ_2

Gaussian std dev = σ_2

How to generate 1D points from this GMM:

1. Flip biased coin (with probability of heads π_1)
2. If heads: sample 1 point from Gaussian mean μ_1, std dev σ_1

   If tails: sample 1 point from Gaussian mean μ_2, std dev σ_2

Example: 1D GMM with *k* Clusters

Cluster 1

Probability of generating a point from cluster 1 = π_1

Gaussian mean = μ_1

Gaussian std dev = σ_1

…

Cluster *k*

Probability of generating a point from cluster k = π_k

Gaussian mean = μ_k

Gaussian std dev = σ_k

How to generate 1D points from this GMM:

1. Flip biased k-sided coin (the sides have probabilities $\pi_1, \ldots, \pi_k$)
2. Let Z be the side that we got (it is some value $1, \ldots, k$)
3. Sample 1 point from Gaussian mean μ_Z, std dev σ_Z
