November 21, 2017
AbSTRACT: We study the polyhedral structure of a generalization of a mixing set described by the intersection of two mixing sets with two shared continuous variables, where one continuous variable has a positive coefficient in one mixing set, and a negative coefficient in the other. Our developments are motivated from a key substructure of linear joint chance-constrained programs (CCPs) with random right hand sides from a finite probability space. The CCPs of interest immediately admit a mixed-integer programming reformulation. Nevertheless, such standard reformulations are difficult to solve at large-scale due to the weakness of their linear programming relaxations. In this paper, we initiate a systemic polyhedral study of such joint CCPs by explicitly analyzing the system obtained from simultaneously considering two linear constraints inside the chance constraint.

We carry out our study on this particular intersection of two mixing sets under a nonnegativity assumption on data. Mixing inequalities are immediately applicable to our set, yet they are not sufficient. Therefore, we propose a new class of valid inequalities in addition to the mixing inequalities, and establish conditions under which these inequalities are facet defining. Moreover, under certain additional assumptions, we prove that these new valid inequalities along with the classical mixing inequalities are sufficient in terms of providing the closed convex hull description of our set. We also show that linear optimization over our set is polynomial-time, and we independently give a (high-order) polynomial-time separation algorithm for the new inequalities. We complement our theoretical results with a computational study on the strength of the proposed inequalities. Our preliminary computational experiments with a fast heuristic separation approach demonstrate that our proposed inequalities are practically effective as well.

Keywords: mixing inequalities; two-sided/joint chance-constraints; convex hull; separation; branch-and-cut

1. Introduction Consider a set $\mathcal{P}$ in the space of the variables $y_{p}, y_{d} \in \mathbb{R}$ and $\mathbf{z} \in \mathbb{R}^{m}$ defined by

$$
\begin{array}{ll}
y_{p}+y_{d}+w_{j} z_{j} \geq w_{j}, & \forall j \in \Omega, \\
y_{p}-y_{d}+\left(v_{j}+u_{d}\right) z_{j} \geq v_{j}, & \forall j \in \Omega, \\
y_{p} \geq 0, & \\
u_{d} \geq y_{d} \geq 0, & \\
\mathbf{z} \in \mathbb{B}^{m}, & \tag{1e}
\end{array}
$$

where $\Omega:=\{1, \ldots, m\}$ is a given set, $w_{j}, v_{j} \in \mathbb{R}$ for $j \in \Omega$ are given data, and $u_{d} \in \mathbb{R}_{+}$is a large finite upper bound on the variable $y_{d}$. Here, the variable $z_{j}, j \in \Omega$ takes a value 1 if constraints (1a)-(1b) need to be trivially satisfied, and it takes a value 0 , otherwise. In this context, the coefficients of $z_{j}$ in (1a)-(1b) are so-called big-M values so that inequalities (1a)-(1b) are trivially satisfied when $z_{j}=1$. Note that for the big-M coefficient of $z_{j}$ in constraint (1b) to be well-defined, we need a finite upper bound on the nonnegative variable $y_{d}$, which we state in constraint (1d).

In this paper, we are primarily interested in the set defined as $\mathcal{P}:=\left\{\left(y_{p}, y_{d}, \mathbf{z}\right) \mid(1 \mathrm{a})-(1 \mathrm{e})\right\}$. The
polyhedral set $\mathcal{P}$ can be viewed as the intersection of two so-called individual mixing sets with shared continuous and binary variables: one mixing set given by the system of inequalities (1a), (1c)-(1e), and the other given by the system of inequalities (1b) and (1c)-(1e). For a single mixing set, a class of so-called mixing inequalities is studied in [5], and this class of inequalities is shown to define the convex hull of solutions to the associated individual mixing set (see also [2]). Since mixing set is a key substructure in multiple applications, such as lot sizing and capacitated facility location, different variants of mixing set have been studied in the literature; see the recent survey [14] and the references therein.

The interaction between the two individual mixing sets in $\mathcal{P}$ through the shared bounded continuous variables $y_{p}$ and $y_{d}$, along with the shared binary variables $\mathbf{z}$, easily lead to a nontrivial structure that has not received much attention in the literature. One exception to this is [6] where the author proposes a blending procedure that takes a weighted sum of multiple individual mixing sets to arrive at another individual mixing set. See [6, 15] for extensions utilizing a cardinality constraint on the binary variables z. However, the valid inequalities based on blending relaxations are not guaranteed to be facet-defining even when the cardinality constraint is relaxed (as we show in Example 2.1). While Küçükyavuz [6] also gives disjunctive programming-based extended formulations for the intersection of mixing sets under a cardinality constraint, the resulting extended formulations are large due to the large number of scenarios and thus they are not effective in practice (see e.g., [13]). Hence, obtaining facet-defining inequalities and an ideal formulation for the convex hull of $\mathcal{P}$ in its original space remain as interesting open questions. In this study, we pursue these questions under some minor assumptions involving nonnegativity of the data $w_{j}, v_{j}$, and $u_{d}$ used in $\mathcal{P}$.

Before we present our results, we give a summary of the notation and conventions used throughout the paper. Given $a \in \mathbb{R}$, we set $(a)_{+}=\max \{a, 0\}$. For a positive integer $n$, we let $[n]=\{1, \ldots, n\}$. We use bold letters to denote vectors. For a vector $\mathbf{x} \in \mathbb{R}^{n}$ and an integer $k \in[n], x_{k}$ denote the $k$-th coordinate of $\mathbf{x}$. We use $\mathbf{0}, \mathbf{1}$ and $\mathbf{e}_{j}$, respectively, to denote the vector of all 0 's, the vector of all 1 's, and the $j$ th unit vector in the appropriate dimension to be understood from the context. Given a set $\mathcal{S}$, we denote its dimension and convex hull by $\operatorname{dim}(\mathcal{S})$ and $\operatorname{conv}(\mathcal{S})$, respectively. Given a vector $\mathbf{a} \in \mathbb{R}^{n}$, we follow the convention $\max _{j \in V} a_{j}=0$ whenever $V=\emptyset$.

While the set we study restricts the coefficients of the common continuous variables $y_{p}, y_{d}$ to either 1 or -1 , we note that the inequalities we derive for $\mathcal{P}$ can be applied to an intersection of mixing sets with more general coefficients and structure for continuous variables. Consider the set given by

$$
\begin{array}{lr}
\left(\mathbf{a}^{1}\right)^{\top} \mathbf{x}+b^{1} y+M_{j}^{1} z_{j} \geq r_{j}^{1}, & \forall j \in \Omega \\
\left(\mathbf{a}^{2}\right)^{\top} \mathbf{x}-b^{2} y+M_{j}^{2} z_{j} \geq r_{j}^{2}, & \forall j \in \Omega \\
\mathbf{x} \geq \mathbf{0}, \quad u \geq y \geq 0, \quad \mathbf{z} \in \mathbb{B}^{m}, & \tag{4}
\end{array}
$$

where $\mathbf{x} \in \mathbb{R}^{n}, y \in \mathbb{R}$ and $\mathbf{z} \in \mathbb{B}^{m}$ are decision variables, and $\mathbf{a}^{1}, \mathbf{a}^{2} \in \mathbb{R}_{+}^{n}$ are arbitrary vectors. In addition, $b^{1}>0$ and $b^{2}>0$ are coefficients of $y$, and $r_{j}^{1}$ and $r_{j}^{2}$ are right-hand side parameters for the first and second sets of inequalities for $j \in \Omega$, respectively. Moreover, to simplify the exposition and without loss of generality, we assume that $\mathbf{x} \geq \mathbf{0}$, and $u \geq y \geq 0$. Hence, we can set $M_{j}^{1}=r_{j}^{1}$, and $M_{j}^{2}=r_{j}^{2}+b^{2} u$. Letting $y_{d}=b^{1} b^{2} y$, and $w_{j}=b^{2} r_{j}^{1}, v_{j}=b^{1} r_{j}^{2}, j \in \Omega$, we obtain a structure generalizing (1a)-(1b) in that the continuous variables with only positive coefficients (i.e., $y_{p}$ ) do not necessarily have the same coefficient in the general mixing set (2)-(4), except when $b^{2} \mathbf{a}^{1}=b^{1} \mathbf{a}^{2}$. In Remark 2.2, we will revisit the set (2)-(4) and discuss how the valid inequalities we propose apply to this more general set. Throughout the paper,
we will mainly restrict our study to the form (1).
Our motivation in studying the structure of $\mathcal{P}$ or its generalization (2)-(4) arose from linear joint chanceconstrained programs (CCPs) with random right-hand side vectors and discrete probability distributions (see, e.g., [12], for an overview of chance-constrained programs). The finite discrete distribution can be an approximation of an unknown continuous distribution, obtained via Sample Average Approximation. Given a finite probability space $\left(\Omega^{\prime}, \mathcal{F}, \mathbb{P}\right)$, a linear joint CCP with right-hand side uncertainty is of the form

$$
\begin{align*}
& \min \xi^{\top} \mathbf{x}  \tag{5a}\\
& \text { s.t. } \mathbb{P}(A \mathbf{x}+\mathbf{b} y \geq \mathbf{r}(\omega)) \geq 1-\epsilon  \tag{5b}\\
& \quad \mathbf{x} \in X \tag{5c}
\end{align*}
$$

where $\mathbf{x} \in \mathbb{R}^{n}$ is the vector of decision variables from a convex compact domain $X, y$ is a decision variable, $\xi$ is the cost vector, and $\epsilon$ is the user-given risk rate. Here $\mathbf{b}$ is a $t$-dimensional vector of coefficients for the variable $y$ with both positive and negative signs, and $A$ is a $t \times n$ matrix with rows $\mathbf{a}^{1}, \ldots, \mathbf{a}^{t}$. In addition, $\mathbf{r}(\omega)$ is the random right-hand side vector that depends on the random variable $\omega \in \Omega$. The chance constraint (5b) enforces that the probability that the solution $\mathbf{x}$ and $y$ satisfies $A \mathbf{x}+\mathbf{b} y \geq \mathbf{r}(\omega)$ should be no less than the risk level $1-\epsilon$.

Let $\Omega:=[m]$ be the index set of elementary events, and $\mathbb{P}\left(\omega_{j}\right)=\delta_{j}$, for all $j \in \Omega$ and $\sum_{j=1}^{m} \delta_{j}=1$. To simplify notation, define $\mathbf{r}_{j}:=\mathbf{r}\left(\omega_{j}\right)$ for all $j \in \Omega$. Then constraint ( 5 b ) is equivalent to

$$
\begin{align*}
& A \mathbf{x}+\mathbf{b} y+M_{j}^{\prime} z_{j} \geq \mathbf{r}_{j}, \quad \forall j \in \Omega  \tag{6a}\\
& \sum_{j \in \Omega} \delta_{j} z_{j} \leq \epsilon  \tag{6b}\\
& \mathbf{z} \in \mathbb{B}^{m} \tag{6c}
\end{align*}
$$

where for all $j \in \Omega, M_{j}^{\prime}$ is a sufficiently large constant that makes (6a) redundant when $z_{j}=1$.
Luedtke et al. [11] observe that the above deterministic equivalent formulation of a single $(t=1)$ linear CCPs with right-hand side uncertainty under finite probability spaces contains a mixing set substructure and propose valid inequalities that strengthen the basic mixing inequalities studied in [5] and [2] by utilizing the cardinality constraint (6b) (see also [6], [1] and [15] for other classes of strong valid inequalities and extended formulations for the individual mixing set intersected with a cardinality/knapsack constraint on the binary variables). Furthermore, mixing inequalities and their extensions derived for linear CCPs under the right-hand side uncertainty assumption have been adapted to more general chance-constrained programs that contain randomness in the technology matrix or those that permit recourse decisions [10, 8]. In contrast to this extensive literature on analyzing and strengthening mixing relaxations associated with a single linear inequality inside a chance-constraint, in this paper we focus on explicitly exploiting the joint CCP structure associated with multiple linear constraints inside a chance constraint where $t \geq 2$ by analyzing the intersection of resulting mixing sets.
1.1 Two-Sided Chance-Constrained Programs A particular form of joint chance constraints, namely a two-sided chance constraint with right hand side uncertainty, is directly connected to our study.

The two-sided chance constraints we consider are of the following form:

$$
\begin{equation*}
\mathbb{P}\left(\left|\mathbf{d}^{\top} \mathbf{x}-h(\omega)\right| \leq \mathbf{p}^{\top} \mathbf{x}-q(\omega)\right) \geq 1-\epsilon \tag{7}
\end{equation*}
$$

where $\mathbf{d}$ and $\mathbf{p}$ are $n$-dimensional coefficient vectors, and $h(\omega)$ and $q(\omega)$ are random parameters that depend on the random variable $\omega \in \Omega^{\prime}$. Note that (7) is nothing but a specific form of a joint chance constraint (5b) because it is precisely

$$
\mathbb{P}\binom{(\mathbf{p}+\mathbf{d})^{\top} \mathbf{x} \geq q(\omega)+h(\omega)}{(\mathbf{p}-\mathbf{d})^{\top} \mathbf{x} \geq q(\omega)-h(\omega)} \geq 1-\epsilon
$$

Two-sided CCPs are the most natural extensions of linear CCPs. While an individual linear CCP with right hand-side uncertainty is easy to handle and can be expressed as a linear program using quantile arguments (see [4]), the linearization of a single chance constraint containing absolute value terms introduce correlation among random variables, and lead to a joint chance-constrained program. Hence, quantile arguments cannot be used to obtain a linear programming representation of a chance-constrained problem containing even a single absolute value term.

When the probability space $\Omega^{\prime}$ is finite, i.e., $\Omega^{\prime}=\left\{\omega_{1}, \ldots, \omega_{m}\right\}$ for some finite integer $m$, problem (5) can be reformulated as a so-called deterministic equivalent program as follows. To simplify notation, let $h_{j}:=h\left(\omega_{j}\right)$ and $q_{j}:=q\left(\omega_{j}\right)$ for all $j \in \Omega$. Let us define the variables $y_{p}=\mathbf{p}^{\top} \mathbf{x}$ and $y_{d}=\mathbf{d}^{\top} \mathbf{x}$ and additional binary variables $\mathbf{z} \in \mathbb{B}^{m}$, one for each scenario in $\Omega$ where $z_{j}=0$ indicates that the relation in the chance constraint is satisfied under scenario $j$. Then inequality (7) can be expressed as follows

$$
\begin{array}{ll}
y_{p}+y_{d}+M_{j}^{1} z_{j} \geq q_{j}+h_{j}, & \forall j \in \Omega, \\
y_{p}-y_{d}+M_{j}^{2} z_{j} \geq q_{j}-h_{j}, & \forall j \in \Omega,  \tag{8b}\\
(6 \mathrm{~b})-(6 \mathrm{c}), &
\end{array}
$$

where for all $j \in \Omega, M_{j}^{1}$ and $M_{j}^{2}$ respectively are chosen sufficiently large to make inequalities (8a) and (8b) redundant when $z_{j}=1$, and (6b)-(6c) enforce that the probability of violating the chance constraint (7) should be less than or equal to $\epsilon$. Because $X$ is a compact set, we can also derive bounds on the new variables $y_{d}=\mathbf{d}^{\top} \mathbf{x}$ and $y_{p}=\mathbf{p}^{\top} \mathbf{x}$. In particular, $l_{d}:=\min _{\mathbf{x} \in X} \mathbf{d}^{\top} \mathbf{x}$ and $u_{d}^{\prime}:=\max _{\mathbf{x} \in X} \mathbf{d}^{\top} \mathbf{x}$. Then $l_{d} \leq y_{d} \leq u_{d}^{\prime}$. Similarly, we have $y_{p} \geq l_{p}$, where $l_{p}:=\min _{\mathbf{x} \in X} \mathbf{p}^{\top} \mathbf{x}$.

Now define $w_{j}:=q_{j}+h_{j}$ and $v_{j}:=q_{j}-h_{j}$ for all $j \in \Omega$. Based on these definitions, we set the big-M values in (8a)-(8b) to $M_{j}^{1}:=w_{j}-l_{p}-l_{d}$ and $M_{j}^{2}:=v_{j}-l_{p}+u_{d}$ for all $j \in \Omega$. In Observation 1.1, we show that without loss of generality, we can assume that $l_{p}=l_{d}=0$. As a result, the constraint set (8) together with (6c), $y_{p} \geq 0$ and (relaxed) bound constraints $0 \leq y_{d} \leq u_{d}$, where $u_{d}:=\max \left\{u_{d}^{\prime}, \max _{j \in \Omega} w_{j}\right\}$, contains the substructure (1) that is the main focus of our study.

ObSERVATION 1.1 Without loss of generality, we can assume that $l_{p}=l_{d}=0$ in the preceding discussion.

Proof. Let $y_{p}^{\prime}=y_{p}+l_{p}$ and $y_{d}^{\prime}=y_{d}+l_{d}$. Define $w_{j}^{\prime}:=w_{j}+l_{p}+l_{d}$ and $v_{j}^{\prime}:=v_{j}+l_{p}-l_{d}$ for all $j \in \Omega$. Consider the set $\mathcal{P}^{\prime}$ defined by the following inequalities:

$$
\begin{array}{ll}
y_{p}^{\prime}+y_{d}^{\prime}+w_{j} z_{j} \geq w_{j}^{\prime}, & \forall j \in \Omega, \\
y_{p}^{\prime}-y_{d}^{\prime}+\left(v_{j}+u_{d}\right) z_{j} \geq v_{j}^{\prime}, & \forall j \in \Omega \\
y_{p}^{\prime} \geq l_{p}, \quad u_{d}+l_{d} \geq y_{d}^{\prime} \geq l_{d}, \quad \mathbf{z} \in \mathbb{B}^{m} . &
\end{array}
$$

For any $\left(y_{p}, y_{d}, \mathbf{z}\right) \in \mathcal{P}$, the corresponding $\left(y_{p}^{\prime}, y_{d}^{\prime}, \mathbf{z}\right) \in \mathcal{P}^{\prime}$ and vice versa.
Unlike the problem structures studied in [11], [6] [1], and [15], the chance constraint (7) involves an absolute value function, which brings more complication in terms of the polyhedral structure of this problem. On a related note, recently, two-sided CCPs with random constraint coefficients are discussed in [3] in the context of energy applications and are studied in [9] under a joint Gaussian distribution assumption.
1.2 Joint Chance-Constrained Programs with Right-Hand Side Uncertainty Next, consider a more general chance-constrained problem given by (5) with $t \geq 2$. Consider (5b) any two rows of $A$, say $\mathbf{a}^{1}$ and $\mathbf{a}^{2}$, and the corresponding elements of $\mathbf{r}_{j}$ denoted by $r_{j}^{1}$ and $r_{j}^{2}$, for all $j \in \Omega$ and the corresponding elements of $\mathbf{b}$ denoted by $b^{1}$ and $b^{2}$, respectively. Suppose that this choice of the two rows of $A$ satisfies $b^{1} \cdot b^{2}<0$. In other words, consider any two inequalities inside the chance constraint such that there exists a variable with a positive coefficient in one row, and a negative coefficient in the other. In this case, constraints (6a)-(6c) are of the desired form (2)-(4).

In a related study, Liu and Küçükyavuz [7] propose valid inequalities for the intersection of multiple mixing sets that appears in probabilistic lot sizing. However, in [7], the constraint matrix inside the chance constraint is a lower triangular matrix of 1's, which is different from the structural form we study.
1.3 Outline The rest of this paper is organized as follows. In Section 2, we introduce our basic setup assumptions and propose a new class of valid inequalities for $\operatorname{conv}(\mathcal{P})$ in addition to the standard mixing inequalities. Section 3 is dedicated to the polyhedral study of $\operatorname{conv}(\mathcal{P})$. In Section 3.1, we examine the inner description of $\operatorname{conv}(\mathcal{P})$, where we prove that $\operatorname{conv}(\mathcal{P})$ is indeed a polyhedral set and thus closed. We establish in Section 3.2 that linear optimization over $\mathcal{P}$ is polynomial-time. We further identify conditions under which our new inequalities are facet-defining for $\operatorname{conv}(\mathcal{P})$ (see Section 3.3) and when they, in addition to the individual mixing inequalities, are sufficient to give the complete linear inequality description of $\operatorname{conv}(\mathcal{P})$ (see Section 3.4). We present a polynomial-time separation algorithm for the proposed inequalities and some heuristic separation approaches in Section 4. Finally, Section 5 reports preliminary numerical results on the computational performance of the proposed inequalities on two-sided CCPs and outlines some future research directions.
2. Problem Setup and Valid Inequalities for the Set $\mathcal{P}$ We start by introducing our basic setup assumptions and then proposing a new class of valid inequalities for the set $\mathcal{P}$. In Section 3.3, we will establish conditions under which these inequalities are facets of $\operatorname{conv}(\mathcal{P})$.

Throughout the paper, we use $\left(y_{p}, y_{d}, \mathbf{z}\right)$ to express points from $\mathcal{P}$. Given a sequence $\Pi=\left\{\pi_{1} \rightarrow \pi_{2} \rightarrow\right.$ $\left.\cdots \rightarrow \pi_{\tau}\right\}$, we also refer to the associated set $\left\{\pi_{1}, \ldots, \pi_{\tau}\right\}$ as $\Pi$; in such cases, whichever interpretation is applicable will be clear within the context.

Next, we make some observations and assumptions on the problem data.

ObSERVATION 2.1 Without loss of generality, we can assume that $w_{j} \geq 0$ for all $j \in \Omega$ in $\mathcal{P}$.

Proof. Define $\Omega^{-}=\left\{j \in \Omega: w_{j}<0\right\}$. For every $j \in \Omega^{-}$, let $z_{j}^{\prime}=1-z_{j}$. For every $j \in \Omega \backslash \Omega^{-}$, we set $z_{j}^{\prime}=z_{j}$. Consider the set $\mathcal{P}^{\prime}$ defined as follows:

$$
y_{p}+y_{d}+w_{j} z_{j}^{\prime} \geq w_{j}, \quad \forall j \in \Omega \backslash \Omega^{-},
$$

$$
\begin{array}{lr}
y_{p}-y_{d}+\left(v_{j}+u_{d}\right) z_{j}^{\prime} \geq v_{j}, & \forall j \in \Omega \backslash \Omega^{-} \\
y_{p}+y_{d}+\left(-w_{j}\right) z_{j}^{\prime} \geq 0, & \forall j \in \Omega^{-} \\
y_{p}-y_{d}+\left(-v_{j}-u_{d}\right) z_{j}^{\prime} \geq-u_{d}, & \forall j \in \Omega^{-} \\
y_{p} \geq 0, \quad u_{d} \geq y_{d} \geq 0, \quad \mathbf{z}^{\prime} \in \mathbb{B}^{m} . &
\end{array}
$$

Then there is a one-to-one correspondence between the vectors in $\mathcal{P}$ and the vectors in $\mathcal{P}^{\prime}$. Moreover, for all $j \in \Omega$, the $w$ coefficient in front of variable $z_{j}^{\prime}$ is nonnegative in the constraints with terms $y_{p}+y_{d}$.

Note that after the transformation, the constraints $y_{p}+y_{d}+\left(-w_{j}\right) z_{j}^{\prime} \geq 0 \forall j \in \Omega^{-}$are redundant because all of the variables are nonnegative and $w_{j} \leq 0$ for $j \in \Omega^{-}$. However, the constraint $y_{p}-y_{d}+\left(-v_{j}-u_{d}\right) z_{j}^{\prime} \geq$ $-u_{d}$ for some $\forall j \in \Omega^{-}$may be non-redundant.

We carry out our polyhedral study of $\operatorname{conv}(\mathcal{P})$ under several assumptions:
A1: $v_{j} \leq w_{j}$ for all $j \in \Omega$;
A2: $0<\max _{j \in \Omega} w_{j} \leq u_{d}$.
First, we show that Assumption A1 is without loss of generality. Suppose there exists $j \in \Omega$ such that $v_{j}>w_{j}$, i.e., Assumption A1 is violated. Note that for any solution in $\mathcal{P}$ such that $z_{j}=1$, both of the constraints (1a) and (1b) for this particular $j$ are redundant. Furthermore, for any solution with $z_{j}=0$, from (1a)-(1b), we must have $y_{p}+y_{d} \geq w_{j}$ and $y_{p}-y_{d} \geq v_{j}$. Then $y_{p} \geq v_{j}+y_{d}>w_{j}-y_{d}$ holds where the last inequality follows from $y_{d} \geq 0$ and $v_{j}>w_{j}$. This then implies that constraint (1a) for this particular $j$ is redundant for the set $\mathcal{P}$ whenever $v_{j}>w_{j}$. Because of the redundancy of the constraint (1a) for any $j \in \Omega$ such that $v_{j}>w_{j}$ in $\mathcal{P}$, in such cases, we can replace $w_{j}$ with $v_{j}$. After this update in data, Assumption A1 holds. Therefore, this assumption is without loss of generality.

Next, in the first part of Assumption A2, in addition to the implication $\max _{j \in \Omega} w_{j} \geq 0$ of Observation 2.1, we further assume that $\max _{j \in \Omega} w_{j}>0$. Otherwise, when $\max _{j \in \Omega} w_{j}=0$, constraint (1a) is redundant because of constraints (1c) and (1d), and the set $\mathcal{P}$ no longer has the desired interesting mixing structure. Hence, throughout the rest of the paper, in order to study interesting cases, we assume $\max _{j \in \Omega} w_{j}>0$. Moreover, in the last part of Assumption A2, the condition $u_{d} \geq \max _{j \in \Omega} w_{j}$ ensures that the upper bound of $y_{d}$ is sufficiently large so that it does not cut off any feasible solution with respect to inequalities (1a), (1c), and (1e).

While it may be possible to have $v_{j}<0$ for some $j \in \Omega$, throughout the rest of this paper, we work with the following assumption that complements Observation 2.1:

A3: $w_{j}$ and $v_{j}$ are nonnegative for all $j \in \Omega$.
However, we note that the nonnegativity of $v_{j}$ is not without loss of generality, as we will show in Example 2.2. Also, note that this assumption is satisfied in the case of joint chance-constrained setting described in Section 1.2 if $r_{j}^{2} \geq 0$ in (3). In other words, the right-hand side of the chance constraint contains nonnegative random data (as in demands, supplies, etc.). In the context of two-sided chance-constrained program described in Section 1.1, this assumption is satisfied if $q_{j} \geq h_{j}$ for all $j \in \Omega$ in (8b).
2.1 Valid Inequalities The set $\mathcal{P}$ has a mixing set substructure, and thus the star inequalities of [2], or the mixing inequalities of [5], can immediately be used to strengthen the formulation of $\mathcal{P}$.

Proposition 2.1 [2, 5] Let $S:=\left\{s_{1} \rightarrow s_{2} \rightarrow \cdots \rightarrow s_{\eta}\right\}$ where $s_{i} \in \Omega$ for all $i \in[\eta]$ be a nonempty sequence such that $w_{s_{1}} \geq w_{s_{2}} \geq \cdots \geq w_{s_{\eta}}$, and define $w_{s_{\eta+1}}=0$. Similarly, let $T:=\left\{t_{1} \rightarrow t_{2} \rightarrow \cdots \rightarrow t_{\rho}\right\}$ where $t_{i} \in \Omega$ for all $i \in[\rho]$ be a nonempty sequence of items such that $v_{t_{1}} \geq v_{t_{2}} \geq \cdots \geq v_{t_{\rho}}$, and define $v_{t_{\rho+1}}=-u_{d}$. Then the following mixing inequalities are valid for $\mathcal{P}$ :

$$
\begin{align*}
& \quad y_{p}+y_{d}+\sum_{j=1}^{\eta}\left(w_{s_{j}}-w_{s_{j+1}}\right) z_{s_{j}} \geq w_{s_{1}}, \quad \text { for the given } S \subseteq \Omega,  \tag{9}\\
& \text { and } \quad y_{p}-y_{d}+\sum_{j=1}^{\rho}\left(v_{t_{j}}-v_{t_{j+1}}\right) z_{t_{j}} \geq v_{t_{1}}, \quad \text { for the given } T \subseteq \Omega . \tag{10}
\end{align*}
$$

Proof. The validity of inequality (9) directly follows from [2] and [5]. In addition, inequality (10) is closely related to the mixing inequalities for the set generated by inequalities (1b) $-(1 \mathrm{~d})$. However, we need to force $v_{t_{\rho+1}}=-u_{d}$, because $y_{p}-y_{d} \geq-u_{d}$, for all $\left(y_{p}, y_{d}, \mathbf{z}\right) \in \mathcal{P}$.

From now on, we let $\alpha$ and $\beta$ be the permutations of indices in $\Omega$ such that $w_{\alpha_{1}} \geq w_{\alpha_{2}} \geq \cdots \geq w_{\alpha_{m}}$, and $v_{\beta_{1}} \geq v_{\beta_{2}} \geq \cdots \geq v_{\beta_{m}}$.

In general, the mixing inequalities are not sufficient to describe $\operatorname{conv}(\mathcal{P})$ because the intersection of the convex hulls of the two mixing sets with two continuous variables as defined in (1a)-(1e) can create new extreme points. We next introduce a new class of valid inequalities for $\mathcal{P}$; we will later on show that these inequalities are facet defining for $\mathcal{P}$ under certain conditions.

Let $\tau \in[m]$, and $\Pi$ be a sequence of $\tau$ items given by $\pi_{1} \rightarrow \pi_{2} \rightarrow \cdots \rightarrow \pi_{\tau}$ where $\pi_{j} \in \Omega$ for all $j \in[\tau]$. Given $\Pi:=\left\{\pi_{1} \rightarrow \pi_{2} \rightarrow \cdots \rightarrow \pi_{\tau}\right\}$, consider the following class of generalized mixing inequalities:

$$
\begin{equation*}
2 y_{p}+\sum_{j=1}^{\tau}\left(\left(w_{\pi_{j}}-\bar{w}_{\Pi, j}\right)_{+}+\left(v_{\pi_{j}}-\bar{v}_{\Pi, j}\right)_{+}\right) z_{\pi_{j}} \geq \bar{w}_{\Pi, 0}+\bar{v}_{\Pi, 0} \tag{11}
\end{equation*}
$$

where

$$
\bar{w}_{\Pi, j}=\left\{\begin{array}{ll}
\max _{j+1 \leq \ell \leq \tau}\left\{w_{\pi_{\ell}}\right\}, & \text { if } j \in[\tau-1] \cup\{0\}, \\
0, & \text { if } j=\tau,
\end{array} \quad \text { and } \quad \bar{v}_{\Pi, j}= \begin{cases}\max _{j+1 \leq \ell \leq \tau}\left\{v_{\pi_{\ell}}\right\}, & \text { if } j \in[\tau-1] \cup\{0\}, \\
0, & \text { if } j=\tau\end{cases}\right.
$$

We define some notation to ease our exposition of the inequality (11). We will use this notation throughout the rest of the paper. For a given $\tau \in[m]$ and a sequence $\Pi:=\left\{\pi_{1} \rightarrow \pi_{2} \rightarrow \cdots \rightarrow \pi_{\tau}\right\}$ where $\pi_{1} \in \Omega$ for all $i \in[\tau]$, we define $R[\Pi] \subseteq \Pi$ to be the subsequence of $\Pi$ given by $r_{1} \rightarrow r_{2} \rightarrow \cdots \rightarrow r_{\tau_{R}}$, with $\tau_{R}:=|R[\Pi]| \leq \tau$, such that for all $j \in\left[\tau_{R}\right], r_{j} \in R[\Pi]$ only if $w_{r_{j}} \geq \bar{w}_{\Pi, k}$, where item $r_{j}$ is the $k$-th item in the sequence $\Pi$, i.e., $r_{j}=\pi_{k}$, for some $k \in[\tau]$. Whenever $\Pi$ is nonempty, from Observation 2.1 and since $\bar{w}_{\Pi, \tau}=0$, we know that $R[\Pi]$ cannot be empty either.

Similarly, let $G[\Pi] \subseteq \Pi$ be a subsequence of $\Pi$ given by $g_{1} \rightarrow g_{2} \rightarrow \cdots \rightarrow g_{\tau_{G}}$, with $\tau_{G}:=|G[\Pi]| \leq \tau$, such that for all $j \in\left[\tau_{G}\right], g_{j} \in G[\Pi]$ only if $v_{g_{j}} \geq \bar{v}_{\Pi, k}$, where $g_{j}$ is the $k$-th item in the sequence $\Pi$, i.e., $g_{j}=\pi_{k}$, for some $k \in[\tau]$. Whenever $\Pi$ is nonempty, from Assumption A3 and since $\bar{v}_{\Pi, \tau}=0$, we know that $G[\Pi]$ cannot be empty either.

Based on these definitions, we have $w_{r_{i}} \geq w_{r_{i+1}}$ for all $i \in\left[\tau_{R}-1\right]$. For each $i \in\left[\tau_{R}-1\right]$, we have $w_{r_{i}} \geq w_{r_{i+1}}$ because $r_{i}=\pi_{k}$ for some $k \in[\tau]$, and $r_{i} \in R[\Pi]$ implies $w_{r_{i}} \geq \bar{w}_{\Pi, k}$. Moreover, because $R[\Pi]$
is a subsequence of $\Pi$, item $r_{i}$ precedes item $r_{i+1}$ in $R[\Pi]$ if and only if $r_{i}$ precedes $r_{i+1}$ in $\Pi$, which implies $\bar{w}_{\Pi, k} \geq w_{r_{i+1}}$. Thus, $w_{r_{i}} \geq \bar{w}_{\Pi, k} \geq w_{r_{i+1}}$. Similarly, we have $v_{g_{i}} \geq v_{g_{i+1}}$, for all $i \in\left[\tau_{G}-1\right]$. Hence, in this notation, inequality (11) is equivalent to

$$
\begin{equation*}
2 y_{p}+\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}+\sum_{j=1}^{\tau_{G}}\left(v_{g_{j}}-v_{g_{j+1}}\right) z_{g_{j}} \geq w_{r_{1}}+v_{g_{1}} \tag{12}
\end{equation*}
$$

where we let $w_{r_{\tau_{R}+1}}=0$, and $v_{g_{\tau_{G}+1}}=0$ for notational convenience.
Proposition 2.2 For a given $\tau \in[m]$ and a sequence $\Pi:=\left\{\pi_{1} \rightarrow \pi_{2} \rightarrow \cdots \rightarrow \pi_{\tau}\right\}$ where $\pi_{i} \in \Omega$ for all $i \in[\tau]$, inequality (11) is valid for $\operatorname{conv}(\mathcal{P})$ under Assumption A3.

Proof. Given $\Pi$, let $R[\Pi], \tau_{R}$, and $G[\Pi], \tau_{G}$ be defined as described above. Then we will focus on inequality (12) that is equivalent to inequality (11). We start by representing the left hand side of (12) in an equivalent form:
$2 y_{p}+\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}+\sum_{j=1}^{\tau_{G}}\left(v_{g_{j}}-v_{g_{j+1}}\right) z_{g_{j}}=y_{p}+y_{d}+\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}+y_{p}-y_{d}+\sum_{j=1}^{\tau_{G}}\left(v_{g_{j}}-v_{g_{j+1}}\right) z_{g_{j}}$.

For a given solution $\left(y_{p}, y_{d}, \mathbf{z}\right) \in \mathcal{P}$, let $j_{1}:=\arg \min _{i \in\left[\tau_{R}\right]}\left\{i \mid z_{r_{i}}=0\right\}$ and $j_{2}:=\arg \min _{i \in\left[\tau_{G}\right]}\left\{i \mid z_{g_{i}}=0\right\}$. First, consider a solution $\left(y_{p}, y_{d}, \mathbf{z}\right)$ such that both $j_{1}$ and $j_{2}$ exist. Then we have $y_{p}+y_{d} \geq w_{r_{j_{1}}}$ and $y_{p}-y_{d} \geq v_{g_{j_{2}}}$ from inequalities (1a) and (1b). Hence, using (13), we deduce

$$
\begin{aligned}
y_{p}+ & y_{d}+\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}+y_{p}-y_{d}+\sum_{j=1}^{\tau_{G}}\left(v_{g_{j}}-v_{g_{j+1}}\right) z_{g_{j}} \\
& \geq w_{r_{j_{1}}}+\sum_{j=1}^{j_{1}-1}\left(w_{r_{j}}-w_{r_{j+1}}\right)+v_{g_{j_{2}}}+\sum_{j=1}^{j_{2}-1}\left(v_{g_{j}}-v_{g_{j+1}}\right)=w_{r_{1}}+v_{g_{1}}
\end{aligned}
$$

and thus inequality (11) is valid for all solutions $\left(y_{p}, y_{d}, \mathbf{z}\right)$ such that both $j_{1}$ and $j_{2}$ exist.
Next, consider a solution $\left(y_{p}, y_{d}, \mathbf{z}\right)$ such that $j_{1}$ does not exist but $j_{2}$ exists. Because $j_{1}$ does not exist and $w_{r_{\tau_{R}+1}}=0$, we have $\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}=w_{r_{1}}$. Also, $y_{p}+y_{d} \geq 0, y_{p}-y_{d} \geq v_{g_{j_{2}}}$, and from (13),

$$
\begin{gathered}
y_{p}+y_{d}+\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}+y_{p}-y_{d}+\sum_{j=1}^{\tau_{G}}\left(v_{g_{j}}-v_{g_{j+1}}\right) z_{g_{j}} \\
\geq 0+w_{r_{1}}+v_{g_{j_{2}}}+\sum_{j=1}^{j_{2}-1}\left(v_{g_{j}}-v_{g_{j+1}}\right)=w_{r_{1}}+v_{g_{1}}
\end{gathered}
$$

This establishes the validity of inequality (11) for solutions such that $j_{2}$ exists and $j_{1}$ does not exist.
Next, consider a solution $\left(y_{p}, y_{d}, \mathbf{z}\right)$ such that $j_{1}$ exists and $j_{2}$ does not exist. Then $z_{r_{j_{1}}}=0$, which implies $y_{p}+y_{d} \geq w_{r_{j_{1}}}$ and $y_{p}-y_{d} \geq v_{r_{j_{1}}}$. Moreover, we deduce $\sum_{j=1}^{\tau_{G}}\left(v_{g_{j}}-v_{g_{j+1}}\right) z_{g_{j}}=v_{g_{1}}$ (because $j_{2}$ does not exist and $v_{g_{\tau_{G}+1}}=0$ ). As a result, using (13), we arrive at:

$$
y_{p}+y_{d}+\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}+y_{p}-y_{d}+\sum_{j=1}^{\tau_{G}}\left(v_{g_{j}}-v_{g_{j+1}}\right) z_{g_{j}}
$$

$$
\begin{aligned}
& \geq w_{r_{j_{1}}}+\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}+v_{r_{j_{1}}}+v_{g_{1}} \\
& \geq w_{r_{j_{1}}}+\sum_{j=1}^{j_{1}-1}\left(w_{r_{j}}-w_{r_{j+1}}\right)+v_{r_{j_{1}}}+v_{g_{1}}=w_{r_{1}}+v_{g_{1}}+v_{r_{j_{1}}} \geq w_{r_{1}}+v_{g_{1}}
\end{aligned}
$$

where the last inequality follows from Assumption A3. Thus, (11) is valid for all such solutions as well.
Finally, consider a solution $\left(y_{p}, y_{d}, \mathbf{z}\right)$ such that that both $j_{1}$ and $j_{2}$ do not exist, then the expression in (13) becomes $2 y_{p}$ and hence the inequality (11) is simply $2 y_{p} \geq 0$ which trivially holds. Therefore, inequality (11) is valid for $\operatorname{conv}(\mathcal{P})$.

Remark 2.1 For a given sequence $\Pi$, from the equivalent representation of inequality (11) given as inequality (12), it is tempting to think that inequality (11) is generated by simply adding up two mixing inequalities (9) and (10) for $S=R[\Pi]$ and $T=G[\Pi]$ respectively. However, whenever $u_{d}$ is positive, the new inequality (11) will indeed be stronger than the inequality obtained by adding the two mixing inequalities (9) for $S=R[\Pi]$ and (10) for $T=G[\Pi]$ because $v_{t_{\rho+1}}=-u_{d}$ in inequality (10) corresponding to the set $T=G[\Pi]$ and $v_{g_{\tau+1}}=0$ in inequality (11) corresponding to the sequence $\Pi$. As a result, inequality (11) can be obtained by adding up two mixing inequalities (9) and (10) for $S=R[\Pi]$ and $T=G[\Pi]$ respectively and then strengthening the coefficient of $z_{\pi_{\tau}}$.

We demonstrate Remark 2.1 more concretely on an example below where we also show that the proposed inequalities are stronger than the mixing inequalities obtained by the blending procedure studied in [6].

Example 2.1 Suppose $\mathcal{P}$ is defined by the data $m=3, u_{d}=10, \mathbf{w}=(8,6,10)$ and $\mathbf{v}=(3,4,2)$. Consider $\Pi:=\{2 \rightarrow 1 \rightarrow 3\}$. Then $R[\Pi]=\{3\}$ and $G[\Pi]=\{2 \rightarrow 1 \rightarrow 3\}$, and the inequality (11) is given by

$$
\begin{aligned}
14 \leq & 2 y_{p}+(6-10)_{+} z_{2}+(4-3)_{+} z_{2}+(8-10)_{+} z_{1}+(3-2)_{+} z_{1}+(10-0)_{+} z_{3}+(2-0)_{+} z_{3} \\
& =2 y_{p}+z_{1}+z_{2}+12 z_{3} .
\end{aligned}
$$

On the other hand, the inequality (9) for $S=R[\Pi]$ is $y_{p}+y_{d}+10 z_{3} \geq 10$, and the inequality (10) for $T=G[\Pi]$ is $y_{p}-y_{d}+z_{1}+z_{2}+12 z_{3} \geq 4$. Note that the sum of the last two inequalities lead to $2 y_{p}+z_{1}+z_{2}+22 z_{3} \geq 14$, which is significantly weaker in terms of the coefficient of $z_{3}$ than the inequality (11) corresponding to $\Pi$.

Next, we show that the proposed generalized mixing inequalities (11) are stronger than the mixing inequalities obtained by the blending procedure studied in [6]. Let $\delta_{1}=y_{p}+y_{d}, \delta_{2}=y_{p}-y_{d}$. Then following [6], we obtain a blended set for $\delta_{1}+\delta_{2}=2 y_{p}$ given by: $\left\{\left(y_{p}, \mathbf{z}\right) \in \mathbb{R}_{+} \times \mathbb{B}^{3}: 2 y_{p}+w_{j}^{\prime} z_{j} \geq w_{j}^{\prime}, j \in[3]\right\}$, where $\mathbf{w}^{\prime}=(11,10,12)=\mathbf{w}+\mathbf{v}$. The blended set is nothing but a mixing set whose convex hull is given by the corresponding mixing inequalities. Furthermore, we can show that none of the facet-defining mixing inequalities for this blended set are facet-defining for $\operatorname{conv}(\mathcal{P})$. For example, the mixing inequality $2 y_{p}+z_{1}+10 z_{2}+z_{3} \geq 12$ for the blended set is dominated by inequality (11) with $\Pi=\{3 \rightarrow 1 \rightarrow 2\}, R[\Pi]=\{3 \rightarrow 1 \rightarrow 2\}, G[\Pi]=\{2\}$ given by $2 y_{p}+2 z_{1}+10 z_{2}+2 z_{3} \geq 14$.

Next, we give a counterexample to the validity of inequality (11) if Assumption A3 is removed.
Example 2.2 Consider an instance of $\mathcal{P}$ defined by the data $m=3, u_{d}=10, \mathbf{w}=(4,2,10), \mathbf{v}=$ $(-3,-4,-5)$. Then Assumption A3 is not satisfied. Note that the point $y_{p}=2.5, y_{d}=7.5, z_{1}=1=$
$z_{2}, z_{3}=0$ is in $\mathcal{P}$. Let us consider $\Pi:=\{3 \rightarrow 1\}$ and the associated inequality (11) for this $\Pi$, i.e., $2 y_{p}+z_{1}+6 z_{3} \geq 7$. The left hand side of this inequality evaluated at the point $y_{p}=2.5, y_{d}=7.5$, $z_{1}=1=z_{2}, z_{3}=0$ is $6 \nsupseteq 7$; thus inequality (11) for this $\Pi$ is not valid for $\mathcal{P}$. Moreover, in this example, $\operatorname{conv}(\mathcal{P})$ contains other facets such as

$$
\begin{aligned}
& 9 y_{p}+y_{d}+6 z_{1}+2 z_{2}+30 z_{3} \geq 38 \\
& 11 y_{p}-y_{d}+6 z_{1}+6 z_{2}+30 z_{3} \geq 32
\end{aligned}
$$

that cannot be described in the form of inequalities (9), (10) or (11).

Due to the unstructured coefficients of the continuous variable $y_{p}$ in facet-defining inequalities in Example 2.2, we restrict our attention to the intersection of two general mixing sets with two continuous variables defined by (1a)-(1e) under Assumption A3.

REmARK 2.2 For the set defined by (2)-(4), whenever $r_{j}^{1}, r_{j}^{2} \geq 0$ for all $j \in \Omega$, we observe that replacing $2 y_{p}$ with $y_{p}^{1}+y_{p}^{2}$, where $y_{p}^{1}:=b_{2} \mathbf{a}_{1}^{\top} \mathbf{x}$ and $y_{p}^{2}:=b_{1} \mathbf{a}_{2}^{\top} \mathbf{x}$ in the proposed inequality (11) and its validity proof, we obtain an inequality that is valid in the context of general joint chance constraints.

Example 2.3 Consider the following example of an intersection of two general mixing sets:

$$
\begin{aligned}
& 2 x+3 y+M_{j}^{1} z_{j} \geq r_{j}^{1}, \quad \forall j \in \Omega \\
& x-2 y+M_{j}^{2} z_{j} \geq r_{j}^{2}, \quad \forall j \in \Omega
\end{aligned}
$$

where $\Omega=[3], \mathbf{r}^{1}=(4,5,8), \mathbf{r}^{2}=(3,2,1), u=10$, and $M_{j}^{1}$ and $M_{j}^{2}$ be set as described right after the system (2)-(4). From Remark 2.2, the adaptation of inequality (11) associated with $\Pi=\{1 \rightarrow 3\}$ is simply $7 x+6 z_{1}+19 z_{3} \geq 25$. In fact, in this example, this inequality is not only valid but also facet-defining.

Next, we study the polyhedral structure of $\operatorname{conv}(\mathcal{P})$. In particular, we establish that $\operatorname{conv}(\mathcal{P})$ can be obtained by adding only the classes of inequalities characterized in (9)-(11) under Assumptions A1-A3.

## 3. Closed Convex Hull of the Set $\mathcal{P}$

3.1 Inner Description of $\operatorname{conv}(\mathcal{P})$ We start with an inner characterization of $\operatorname{conv}(\mathcal{P})$ under Assumptions A1-A3 by identifying its extreme points and extreme rays. Because $\operatorname{conv}(\mathcal{P})$ is convex hull of finitely many extreme points and extreme rays, it is a polyhedral set and thus closed.

First, we present several results that are used to conduct our polyhedral study.

Observation 3.1 Consider a point $\left(\bar{y}_{p}, \bar{y}_{d}, \overline{\mathbf{z}}\right) \in \mathcal{P}$. Define the set $V(\overline{\mathbf{z}}):=\left\{j \in[m]: \bar{z}_{j}=0\right\}$.
(i) For any $j^{\prime} \in V(\overline{\mathbf{z}})$, the point $\left(\bar{y}_{p}, \bar{y}_{d}, \overline{\mathbf{z}}+\mathbf{e}_{j^{\prime}}\right)$ is also in $\mathcal{P}$.
(ii) For any $j^{\prime} \in[m] \backslash V(\overline{\mathbf{z}})$, whenever $\bar{y}_{d}=0$, the point $\left(\max \left\{\bar{y}_{p}, w_{j^{\prime}}\right\}, 0, \overline{\mathbf{z}}-\mathbf{e}_{j^{\prime}}\right)$ is also in $\mathcal{P}$.
(iii) For any $\triangle>0$, the point $\left(\bar{y}_{p}+\triangle, \bar{y}_{d}, \overline{\mathbf{z}}\right)$ is also in $\mathcal{P}$.

Proof. Given $\left(\bar{y}_{p}, \bar{y}_{d}, \overline{\mathbf{z}}\right) \in \mathcal{P}$, let $V:=V(\overline{\mathbf{z}})$, i.e., $j \in V$ if and only if $\bar{z}_{j}=0$.
(i) Since $\left(\bar{y}_{p}, \bar{y}_{d}, \overline{\mathbf{z}}\right) \in \mathcal{P}$, we have $\bar{y}_{p}+\bar{y}_{d} \geq \max _{j \in V} w_{j}, \bar{y}_{p}-\bar{y}_{d} \geq \max _{j \in V} v_{j}, \bar{y}_{p} \geq 0$, and $u_{d} \geq$ $\bar{y}_{d} \geq 0$. Then for any $j^{\prime} \in V$, the point ( $\bar{y}_{p}, \bar{y}_{d}, \overline{\mathbf{z}}+\mathbf{e}_{j^{\prime}}$ ) satisfies inequalities (1a) and (1b) because $\max _{j \in V} w_{j} \geq \max _{j \in V \backslash\left\{j^{\prime}\right\}} w_{j}$, and $\max _{j \in V} v_{j} \geq \max _{j \in V \backslash\left\{j^{\prime}\right\}} v_{j}$. Also, because $\bar{y}_{p}$ and $\bar{y}_{d}$ remain the same, inequalities (1c)-(1e) are also trivially satisfied. Hence, ( $\left.\bar{y}_{p}, \bar{y}_{d}, \overline{\mathbf{z}}+\mathbf{e}_{j^{\prime}}\right)$ is also in $\mathcal{P}$.
(ii) Since $\left(\bar{y}_{p}, 0, \overline{\mathbf{z}}\right) \in \mathcal{P}$, we have $\bar{y}_{p} \geq \max _{j \in V} w_{j}, \bar{y}_{p} \geq \max _{j \in V} v_{j}$. Hence, $\max \left\{\bar{y}_{p}, w_{j^{\prime}}\right\} \geq$ $\max _{j \in V \cup\left\{j^{\prime}\right\}} w_{j} \geq \max _{j \in V \cup\left\{j^{\prime}\right\}} v_{j}$ where the last inequality follows from Assumption A1, and $\max \left\{\bar{y}_{p}, w_{j^{\prime}}\right\} \geq 0$ holds because $\bar{y}_{p} \geq 0$. Thus, inequalities (1a)-(1c) are satisfied. Inequalities (1d) and (1e) are also trivially satisfied. Hence, the point $\left(\max \left\{\bar{y}_{p}, w_{j^{\prime}}\right\}, 0, \overline{\mathbf{z}}-\mathbf{e}_{j^{\prime}}\right)$ is also in $\mathcal{P}$.
(iii) This part follows because there are no constraints in $\mathcal{P}$ that impose an upper bound on $y_{p}$.

Next, we present classes of points that are critical in our convex hull characterization and polyhedral study. Recall our convention that for $V=\emptyset$ and $\mathbf{a} \in \mathbb{R}^{n}$, we define $\max _{j \in V} a_{j}=0$.

Lemma 3.1 The following points are in $\mathcal{P}$ :

$$
\begin{array}{rlr}
A(V): & \left(\max _{j \in V} w_{j}, 0, \sum_{j \in \Omega \backslash V} \mathbf{e}_{j}\right), & V \subseteq \Omega, \\
B(V):\left(\max _{j \in V} v_{j}+u_{d}, u_{d}, \sum_{j \in \Omega \backslash V} \mathbf{e}_{j}\right), & V \subseteq \Omega, \\
C(V): & \left(\frac{\max _{j \in V} w_{j}+\max _{j \in V} v_{j}}{2}, \frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}, \sum_{j \in \Omega \backslash V} \mathbf{e}_{j}\right), & V \subseteq \Omega, \\
D: & \left(0, u_{d}, \mathbf{1}\right), & \tag{14d}
\end{array}
$$

where $A(\emptyset)=C(\emptyset)=(0,0, \mathbf{1})$ and $B(\emptyset)=\left(u_{d}, u_{d}, \mathbf{1}\right)$.

Proof. The points listed above satisfy inequality (1e) trivially. Moreover, because $u_{d}>0$ (from Assumption A2), all of the points $A(V)$ for $V \subseteq \Omega, B(V)$ for $\emptyset \neq V \subseteq \Omega$, and $D$ immediately satisfy inequalities (1d). The points $C(V)$ for $V \subseteq \Omega$ also satisfy inequalities (1d) because $u_{d} \geq \max _{j \in V} w_{j} \geq$ $\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2} \geq 0$ holds from Assumptions A2, A3, and A1, respectively.

The point $D$ satisfies inequalities (1c) trivially. It also satisfies inequalities (1a)-(1b) because $u_{d}>0$. Clearly, $A(\emptyset) \in \mathcal{P}$. For a given $\emptyset \neq V \subseteq \Omega$, starting from the fact that $A(\emptyset) \in \mathcal{P}$ and repeatedly applying Observation 3.1(ii) for the indices $j \in V$, we observe that the point $A(V)$ is feasible. Next, the point $B(V)$, for any $V \subseteq \Omega$, satisfies inequalities (1a) and (1b), because $y_{p}+y_{d}=2 u_{d}+\max _{j \in V} v_{j}>\max _{j \in V} w_{j}$ from Assumptions A3 (or A1) and A2, and $y_{p}-y_{d}=\max _{j \in V} v_{j}$, respectively. In addition, $B(V)$ also satisfies (1c) since $u_{d} \geq \max _{j \in V} w_{j} \geq \max _{j \in V} v_{j}$ from Assumptions A1 and A2. Finally, the point $C(V)$, for any $V \subseteq \Omega$, satisfies (1a) and (1b), because $y_{p}+y_{d}=\max _{j \in V} w_{j}$, and $y_{p}-y_{d}=\max _{j \in V} v_{j}$, respectively. Furthermore, $C(V)$ also satisfies (1c) from Assumption A3

Note that for any $V \subseteq \Omega$ such that $\max _{j \in V} w_{j}=\max _{j \in V} v_{j}$ we have $A(V)=C(V)$. In such cases, we may classify such a point as an $A$ point or $C$ point, and our classification will be clear based on the context.

Remark $3.1 \quad(i)$ Assumptions A2 and A3 imply $u_{d}>\frac{1}{2}\left(\max _{j \in V} w_{j}-\max _{j \in V} v_{j}\right)$, for all $V \subseteq \Omega$.
(ii) Assumption A1 implies $\max _{j \in V} w_{j} \geq \max _{j \in V} v_{j}$ for any $V \subseteq \Omega$.
(iii) If $\max _{j \in V} w_{j}=\max _{j \in V} v_{j}$ for a given $V \subseteq \Omega$, then it can been seen that the corresponding points $A(V)$ and $C(V)$ are the same. In such a case, all of the inequalities tight at $A(V)$ are also tight at $C(V)$, and thus if $A(V)$ is an optimal solution, then so is $C(V)$.

The points in Lemma 3.1 are useful in characterization of the extreme points of $\operatorname{conv}(\mathcal{P})$.
Proposition 3.1 The only recessive direction of $\operatorname{conv}(\mathcal{P})$ is $(1,0, \mathbf{0})$. The extreme points of $\operatorname{conv}(\mathcal{P})$ are among $A(V)$ and $C(V)$, for all $V \subseteq \Omega, B(V)$, for all $\emptyset \neq V \subseteq \Omega$, and $D$, as defined in (14a)-(14d).

Proof. From Observation 3.1(iii), $(1,0,0)$ is a recessive direction of $\mathcal{P}$. Moreover, there are no other recessive directions of $\operatorname{conv}(\mathcal{P})$ because $y_{p}$ is bounded from below, and $y_{d}$ and $\mathbf{z}$ are bounded from above and below. In addition, from Lemma 3.1, the points $A(V), B(V), C(V)$ for some $V \subseteq \Omega$ and $D$ are in $\mathcal{P}$.

First, observe that the only extreme points of $\operatorname{conv}(\mathcal{P})$ where $z_{j}=1$ for all $j \in \Omega$ are $D=\left(0, u_{d}, \mathbf{1}\right)$ and $A(\emptyset)=C(\emptyset)=(0,0, \mathbf{1})$, because $B(\emptyset)=D+u_{d}(1,0, \mathbf{0})$. Point $D$ is extreme because it satisfies inequalities $y_{p} \geq 0, y_{d} \leq u_{d}$ and $z_{j} \leq 1$ for all $j \in \Omega$ at equality, and these inequalities are linearly independent. Similarly, $A(\emptyset)$ satisfies $y_{p} \geq 0, y_{d} \geq 0$ and $z_{j} \leq 1$ for all $j \in \Omega$ at equality, and these inequalities are linearly independent. Next, for a fixed $\emptyset \neq V \subseteq \Omega$, let $\widehat{\mathcal{P}}(V)$ be the polyhedron obtained from $\mathcal{P}$ by enforcing the restriction $\mathbf{z}=\sum_{j \in \Omega \backslash V} \mathbf{e}_{j}$, i.e., $\widehat{\mathcal{P}}(V)$ is the convex hull of feasible points of form $\left(y_{p}, y_{d}, \sum_{j \in \Omega \backslash V} \mathbf{e}_{j}\right)$, i.e.,

$$
\widehat{\mathcal{P}}(V):=\left\{\left(y_{p}, y_{d}, \sum_{j \in \Omega \backslash V} \mathbf{e}_{j}\right) \mid y_{p}+y_{d} \geq \max _{j \in V} w_{j}, y_{p}-y_{d} \geq \max _{j \in V} v_{j}, y_{p} \geq 0, u_{d} \geq y_{d} \geq 0\right\} .
$$

t For a given $\emptyset \neq V \subseteq \Omega$, under Assumptions A1, A2 and A3, Figure 1 illustrates the projection of the region $\widehat{\mathcal{P}}(V)$ onto the space of $\left(y_{p}, y_{d}\right)$ when $\max _{j \in V} w_{j}>\max _{j \in V} v_{j} \geq 0$. Recall that when $\max _{j \in V} w_{j}=$ $\max _{j \in V} v_{j}$ we have $A(V)=C(V)$. Next, we prove the extreme points of $\widehat{\mathcal{P}}(V)$ formally.

First note that we have only two variables $y_{p}, y_{d}$ in $\widehat{\mathcal{P}}(V)$, hence each extreme point of $\widehat{\mathcal{P}}(V)$ is characterized by at least two active linear inequalities. Therefore, it suffices to consider pairs of constraints and identify the resulting situation in terms of feasibility vs infeasibility of the point, and categorize the point whenever it is feasible. We summarize these possibilities in Table 1, where an entry "I" indicates that the combination of active inequalities yield an infeasible point. Next, we explain each entry in the upper triangular part of Table 1.

- When the constraints $y_{p}-y_{d} \geq \max _{j \in V} v_{j}$ and $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$ are simultaneously active, we obtain $y_{p}=\frac{\max _{j \in V} w_{j}+\max _{j \in V} v_{j}}{2}$ and $y_{d}=\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}$ which is a point of form $C(V)$.
- Let us explain why it is not possible to have the constraints $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$ and $y_{p} \geq 0$ be simultaneously active at a feasible extreme point of $\widehat{\mathcal{P}}(V)$. When these constraints are simultaneously active, we have $y_{d}=\max _{j \in V} w_{j}>0$ due to our Assumption A2. But, then the point $\left(y_{p}, y_{d}\right)=\left(0, \max _{j \in V} w_{j}\right)$ violates the constraint that $y_{p}-y_{d} \geq \max _{j \in V} v_{j}$ because of our Assumption A2 which ensures $v_{j} \geq 0$.
- If both $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$ and $y_{d} \leq u_{d}$ are simultaneously active, then we have $y_{d}=u_{d}$ and $y_{p}=\max _{j \in V} w_{j}-u_{d} \leq 0$ because of Assumption A2. This violates the constraint $y_{p} \geq 0$.
- When the constraints $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$ and $y_{d} \geq 0$ are simultaneously active, we obtain $y_{p}=\max _{j \in V} w_{j}$ and $y_{d}=0$, which is a point of form $A(V)$.
- If the constraints $y_{p}-y_{d} \geq \max _{j \in V} v_{j}$ and $y_{p} \geq 0$ are simultaneously active, then we get $y_{p}=0$ and $y_{d}=-\max _{j \in V} v_{j} \leq 0$ from Assumption A3. Therefore, in this case either the point is infeasible because it violates the constraint $y_{d} \geq 0$ or the constraint $y_{d} \geq 0$ is also active. When the constraints $y_{p} \geq 0$ and $y_{d} \geq 0$ are simultaneously active, the constraint $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$ is violated because of Assumption A2.
- When the constraints $y_{p}-y_{d} \geq \max _{j \in V} v_{j}$ and $y_{d} \leq u_{d}$ are simultaneously active, we obtain $y_{d}=u_{d}$ and $y_{p}=\max _{j \in V} v_{j}+u_{d}$, which is a point of the form $B(V)$.
- If the constraints $y_{p}-y_{d} \geq \max _{j \in V} v_{j}$ and $y_{d} \geq 0$ are simultaneously active, we obtain $y_{d}=$ 0 and $y_{p}=\max _{j \in V} v_{j} \leq \max _{j \in V} w_{j}$ from Assumption A1. There are two cases to consider. If $\max _{j \in V} w_{j}>\max _{j \in V} v_{j}$, then this point is infeasible, because it violates the constraint that $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$. If $\max _{j \in V} w_{j}=\max _{j \in V} v_{j}$, then we obtain a point of the form $A(V)=C(V)$.
- If $y_{p} \geq 0$ and $y_{d} \leq u_{d}$ are simultaneously active, then we have $y_{d}=u_{d}$ and $y_{p}=0$, which violates the constraint $y_{p}-y_{d} \geq \max _{j \in V} v_{j}$ because of Assumptions A2 and A3.
- If $y_{p} \geq 0$ and $y_{d} \geq 0$ are simultaneously active, then we have $y_{p}=y_{d}=0$. From Assumptions A2, we have $\max _{j \in V} w_{j}>0$. Then this point violates the constraint $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$.
- Clearly, both $y_{d} \geq 0$ and $y_{d} \leq u_{d}$ cannot be simultaneously active because $u_{d}>0$ from Assumption A2.

We then immediately observe from Figure 1, Table 1 and the discussion above that $A(V), B(V)$, and $C(V)$ are the only extreme points of $\widehat{\mathcal{P}}(V)$. Note that $\mathcal{P}=D \cup A(\emptyset) \cup(\underset{\emptyset \neq V \subseteq \Omega}{\bigcup} \widehat{P}(V))$ and the recessive

Figure 1: Projection of $\widehat{\mathcal{P}}(V)$ onto the space of $\left(y_{p}, y_{d}\right)$ under Assumptions A1, A2 and A3.
direction of $\widehat{P}(V)$ for any $V \subseteq \Omega$ is $(1,0, \mathbf{0})$ for all $\emptyset \neq V \subseteq \Omega$. As a result, $\operatorname{conv}(\mathcal{P})$ is simply convex combinations of the points of the form $A(V), C(V)$, for some $V \subseteq \Omega, B(V)$ for some $\emptyset \neq V \subseteq \Omega$, and $D$, and conical combination of $(1,0,0)$.
3.2 Complexity of Linear Optimization over $\mathcal{P}$ Next, we address the complexity of optimizing a linear objective over $\mathcal{P}$. Given a linear objective function $\left(c_{p}, c_{d}, \mathbf{f}\right)$, we denote the cost of a given solution $\left(y_{p}, y_{d}, \mathbf{z}\right)$ by $F\left(\left(y_{p}, y_{d}, \mathbf{z}\right)\right):=c_{p} y_{p}+c_{d} y_{d}+\mathbf{f}^{\top} \mathbf{z}$.

Table 1: Extreme points of Projection of $\widehat{\mathcal{P}}(V)$ onto the space of $\left(y_{p}, y_{d}\right)$.

| Combination | $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$ | $y_{p}-y_{d} \geq \max _{j \in V} v_{j}$ | $y_{p} \geq 0$ | $y_{d} \leq u_{d}$ | $y_{d} \geq 0$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $y_{p}+y_{d} \geq \max _{j \in V} w_{j}$ | - | $C$ (V) | I | I | $A(V)$ |
| $y_{p}-y_{d} \geq \max _{j \in V} v_{j}$ | $C(V)$ | - | I | $B(V)$ | I or $A(V)=C(V)$ |
| $y_{p} \geq 0$ | I | 1 | - | I | I |
| $y_{d} \leq u_{d}$ | I | $B(V)$ | I | - | I |
| $y_{d} \geq 0$ | A(V) | I | I | I | - |

Proposition 3.2 Let $\left(c_{p}, c_{d}, \mathbf{f}\right)$ be an arbitrary nonzero cost vector. Then the optimization problem $\left\{\min _{\left(y_{p}, y_{d}, \mathbf{z}\right) \in \mathcal{P}} c_{p} y_{p}+c_{d} y_{d}+\mathbf{f}^{\top} \mathbf{z}\right\}$ can be solved in $O\left(m^{3}\right)$ time.

Proof. Note that if the problem is not unbounded (i.e., $c_{p} \geq 0$ ), then there exists an optimal solution that is an extreme point of $\operatorname{conv}(\mathcal{P})$. Let $V_{A}^{*} \subseteq \Omega$ be such that $V_{A}^{*}:=\arg \min _{V \subseteq \Omega} F(A(V))$, in other words, $A\left(V_{A}^{*}\right)$ is a solution among all solutions of the form $A(V)$ that gives the minimum objective. Define $V_{B}^{*}$ and $V_{C}^{*}$ similarly for the solutions of the form $B(V)$ and $C(V)$, respectively. Then the optimal solution is given by $\min \left\{F\left(A\left(V_{A}^{*}\right)\right), F\left(B\left(V_{B}^{*}\right)\right), F\left(C\left(V_{C}^{*}\right)\right), F(D)\right\}$. Finding $V_{A}^{*}$ and $V_{B}^{*}$ takes $O(m \log m)$ time, because this is equivalent to optimizing over the mixing set (see [2, 5]). Hence, we address the complexity of finding $V_{C}^{*}$. Recall that $A(\emptyset)=C(\emptyset)$. Therefore, we consider a slightly different problem of finding $V_{C}^{*}:=\arg \min _{\emptyset \neq V \subseteq \Omega} F(C(V))$.

For any $V$ satisfying $\emptyset \neq V \subseteq \Omega$, let the indices $i_{V}, j_{V}$ be defined as $i_{V}=\arg \max _{i \in V} w_{i}$ and $j_{V}=$ $\arg \max _{i \in V} v_{i}$. Then both $i_{V}, j_{V}$ belong to $V$, and they satisfy $w_{i_{V}} \geq w_{j_{V}}$ and $v_{j_{V}} \geq v_{i_{V}}$. We will partition the points $C(V)$ where $\emptyset \neq V \subseteq \Omega$ based on their two indices $i_{V}, j_{V}$. For $i, j \in \Omega$ such that $w_{i} \geq w_{j}$ and $v_{j} \geq v_{i}$, we define $\Omega_{i j}:=\left\{k \in \Omega: w_{k} \leq w_{i}, v_{k} \leq v_{j}\right\}$ and let $G(i, j)$ be the objective value of the best extreme point of form $C(V)$, for some set $V$ satisfying $\{i, j\} \subseteq V \subseteq \Omega_{i, j}$. From the definition of $\Omega_{i, j}$, we have $w_{i}=\max _{\ell \in V} w_{\ell}$ and $v_{j}=\max _{\ell \in V} v_{\ell}$ for any set $V$ satisfying $\{i, j\} \subseteq V \subseteq \Omega_{i, j}$. Therefore, for fixed $i, j \in \Omega$, we have

$$
\begin{equation*}
G(i, j)=\min _{\{i, j\} \subseteq V \subset \Omega_{i j}}\left\{c_{p} \frac{w_{i}+v_{j}}{2}+c_{d} \frac{w_{i}-v_{j}}{2}+\sum_{\ell \in(\Omega \backslash V)} f_{\ell}\right\} . \tag{15}
\end{equation*}
$$

Next, we show that for given $i, j \in \Omega$ such that $w_{i} \geq w_{j}$ and $v_{j} \geq v_{i}$, the optimal set $V_{i j} \subseteq \Omega_{i j}$ minimizing (15) can be found in polynomial time. From the definition of $G(i, j)$ in (15), we have $i, j \in V_{i j}$. For all $\ell \in \Omega$ such that $w_{\ell}>w_{i}$ or $v_{\ell}>v_{j}$, the definition of $\Omega_{i j}$ implies $\ell \notin V_{i j}$. Next, for all $\ell \in \Omega$ such that $\ell \neq i, j$, and $w_{\ell} \leq w_{i}$, and $v_{\ell} \leq v_{j}$, if $f_{\ell}>0$, we must have $\ell \notin V_{i j}$ to minimize the cost. Otherwise, if $f_{\ell} \leq 0$, we let $\ell \in V_{i j}$. Hence, for a fixed $i, j \in \Omega$, we can find the optimal $G(i, j)$ in $\mathrm{O}(m)$ time. Finally, $V_{C}^{*}=V_{i^{*} j^{*}}$, where $\left(i^{*}, j^{*}\right)=\arg \min _{i, j \in \Omega} G(i, j)$. Thus, the overall complexity is $O\left(m^{3}\right)$.

While Proposition 3.2 brings good news by demonstrating an efficient algorithm to optimize over $\mathcal{P}$, in the cases where $\mathcal{P}$ arises as a substructure, such as our motivation originating from two-sided (or joint) chance constrained optimization problems, we cannot immediately use Proposition 3.2. On the other hand, strong valid inequalities for $\mathcal{P}$ can immediately be employed in the cases where $\mathcal{P}$ arises as a substructure. Consequently, we examine the strength of the inequalities (9)-(11).
3.3 When are Inequalities (9)-(11) Facets of $\operatorname{conv}(\mathcal{P})$ ? In this section, we establish conditions under which inequalities (9)-(11) are facet-defining for $\operatorname{conv}(\mathcal{P})$ under Assumptions A1-A3.

We first establish that $\operatorname{conv}(\mathcal{P})$ is full dimensional under Assumptions A1 and A2.
Proposition 3.3 Consider the points $A(\emptyset), A(\Omega), B(\Omega),\left(w_{\alpha_{1}}, 0, \mathbf{e}_{j}\right)$ for all $j \in \Omega \backslash\left\{\alpha_{1}\right\}$, and $\left(w_{\alpha_{1}}+\right.$ $\triangle, 0, \mathbf{0})$, where $\triangle>0$ is a small number. All of these points are in $\mathcal{P}$. Moreover, $\operatorname{dim}(\operatorname{conv}(\mathcal{P}))=m+2$.

Proof. Lemma 3.1 implies that $A(\emptyset), A(\Omega)$ and $B(\Omega)$ are feasible. Next, using Observation 3.1(i) starting from $A(\Omega)=\left(w_{\alpha_{1}}, 0, \mathbf{0}\right)$, we deduce the point ( $w_{\alpha_{1}}, 0, \mathbf{e}_{j}$ ), for all $j \in \Omega \backslash\left\{\alpha_{1}\right\}$, is feasible. Also, the feasibility of the point $A(\Omega)$ along with Observation 3.1(iii) proves that the point ( $w_{\alpha_{1}}+\triangle, 0, \mathbf{0}$ ) is feasible.

Let us denote $P_{0}:=A(\Omega)=\left(w_{\alpha_{1}}, 0, \mathbf{0}\right), P_{1}:=A(\emptyset)=(0,0, \mathbf{1}), P_{2}:=\left(w_{\alpha_{1}}+\triangle, 0, \mathbf{0}\right), P_{2+i}:=\left(w_{\alpha_{1}}, 0, \mathbf{e}_{j}\right)$, for all $i \in[m-1]$ and $j \in \Omega \backslash\left\{\alpha_{1}\right\}$, and $P_{m+2}:=B(\Omega)=\left(v_{\beta_{1}}+u_{d}, u_{d}, \mathbf{0}\right)$. Then $P_{i}-P_{0}$, for all $i \in[m+2]$ are linearly independent. Hence, $P_{i}$, for all $i \in[m+2] \cup\{0\}$, are affinely independent.

Let us next examine the mixing inequalities (9) and (10). Recall our convention that $\alpha$ and $\beta$ are the permutations of indices in $\Omega$ such that $w_{\alpha_{1}} \geq w_{\alpha_{2}} \geq \cdots \geq w_{\alpha_{m}}$, and $v_{\beta_{1}} \geq v_{\beta_{2}} \geq \cdots \geq v_{\beta_{m}}$.

Proposition 3.4 Consider the setup of Proposition 2.1 with the nonempty sequences $S=\left\{s_{1} \rightarrow s_{2} \rightarrow\right.$ $\left.\cdots \rightarrow s_{\eta}\right\}$ and $T=\left\{t_{1} \rightarrow t_{2} \rightarrow \cdots \rightarrow t_{\rho}\right\}$ as described there. Inequalities (9) and (10) associated $S$ and $T$ are facet-defining for $\operatorname{conv}(\mathcal{P})$ if and only if $w_{s_{1}}=w_{\alpha_{1}}$, and $v_{t_{1}}=v_{\beta_{1}}$, respectively.

Proof. See Appendix A.
Next, we study the strength of the proposed inequalities (11).

Proposition 3.5 Consider the setup of Proposition 2.2 and the associated notation preceding it. Given $\tau \in[m]$ and a sequence $\Pi:=\left\{\pi_{1} \rightarrow \pi_{2} \rightarrow \cdots \rightarrow \pi_{\tau}\right\}$ where $\pi_{j} \in \Omega$ for all $j \in[\tau]$. Then inequality (11) is facet-defining for $\operatorname{conv}(\mathcal{P})$ if and only if $w_{r_{1}}=w_{\alpha_{1}}$ and $v_{g_{1}}=v_{\beta_{1}}$.

Proof. See Appendix B.
Example 2.1 (continued). Note that in this example, $\alpha_{1}=3$ with $w_{\alpha_{1}}=10$, and $\beta_{1}=2$ with $v_{\beta_{1}}=4$. Once again consider the inequality $2 y_{p}+z_{2}+z_{1}+12 z_{3} \geq 14$ derived for $\Pi=\{2 \rightarrow 1 \rightarrow 3\}$. Recall that in this case $R[\Pi]=\{3\}=:\left\{r_{1}\right\}$ and $G[\Pi]=\{2 \rightarrow 1 \rightarrow 3\}=:\left\{g_{1} \rightarrow g_{2} \rightarrow g_{3}\right\}$. Hence, $r_{1}=3$ and $g_{1}=2$. Because $w_{r_{1}}=w_{\alpha_{1}}$ and $v_{g_{1}}=v_{\beta_{1}}$, we deduce that this inequality is facet-defining.
3.4 Outer Description of $\operatorname{conv}(\mathcal{P})$ In this section, we shift our focus to the outer (complete linear inequality) description of $\operatorname{conv}(\mathcal{P})$. We establish the sufficiency of inequalities (9)-(11) along with bound constraints for describing the closed convex hull of $\mathcal{P}$ under our Assumptions A1, A2, and A3. In particular, we have the following main result of this section - the linear inequality description of $\operatorname{conv}(\mathcal{P})$.

Theorem 3.1 Under Assumptions A1, A2 and A3, the set $\operatorname{conv}(\mathcal{P})$ is completely described by inequalities (1c)-(1d),(9)-(11), and

$$
\begin{equation*}
0 \leq z_{j} \leq 1 \quad \forall j \in \Omega \tag{16}
\end{equation*}
$$

The inner characterization of $\operatorname{conv}(\mathcal{P})$ established in Proposition 3.1 and the associated point structure identified in Lemma 3.1 form the basis of our developments to prove Theorem 3.1. Several observations and
lemmas pertaining to the point structure identified in Lemma 3.1 are used in the proof of Theorem 3.1. We start by presenting these results.

In our developments for Theorem 3.1, given two subsets $V_{1}$ and $V_{2}$ of $\Omega$ and a vector $\mathbf{a} \in \mathbb{R}^{m}$, we will frequently refer to the function $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)$ defined as

$$
\psi\left(\mathbf{a}, V_{1}, V_{2}\right):=\min \left\{\max _{j \in V_{1}} a_{j}, \max _{j \in V_{2}} a_{j}\right\}-\max _{j \in V_{1} \cap V_{2}} a_{j}
$$

Note that $\psi(\mathbf{a}, V, V)=0$ for any $V$ and any a. Moreover, for any $\mathbf{a}$, if $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)>0$, then $V_{1} \neq V_{2}$.
We next present a few observations related to this function $\psi(\cdot)$. These observations form the building blocks of comparisons of the objective values of various sets of points of form $A(V), B(V)$, and $C(V)$ for some $V \subseteq \Omega$ in our analysis of optimal points for a given objective vector.

ObSERVATION 3.2 Let $V_{1}, V_{2} \subseteq \Omega$. Then for any vector $\mathbf{a} \in \mathbb{R}^{m}$, we have $\psi\left(\mathbf{a}, V_{1}, V_{2}\right) \geq 0$ and

$$
\begin{equation*}
\max _{j \in V_{1} \cup V_{2}} a_{j} \leq \max _{j \in V_{1}} a_{j}+\max _{j \in V_{2}} a_{j}-\max _{j \in V_{1} \cap V_{2}} a_{j} \tag{17}
\end{equation*}
$$

Inequality (17) holds at equality if and only if $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)=0$. In addition, if $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)>0$, then $V_{1} \neq V_{2}$, inequality (17) is strict, and both $V_{1}$ and $V_{2}$ are nonempty.

Proof. Because $\max _{j \in V_{1}} a_{j} \geq \max _{j \in V_{1} \cap V_{2}} a_{j}$, and similarly $\max _{j \in V_{2}} a_{j} \geq \max _{j \in V_{1} \cap V_{2}} a_{j}$, we have $\min \left\{\max _{j \in V_{1}} a_{j}, \max _{j \in V_{2}} a_{j}\right\} \geq \max _{j \in V_{1} \cap V_{2}} a_{j}$. This implies $\psi\left(\mathbf{a}, V_{1}, V_{2}\right) \geq 0$. Moreover,

$$
\begin{aligned}
\max _{j \in V_{1} \cup V_{2}} a_{j}=\max \left\{\max _{j \in V_{1}} a_{j}, \max _{j \in V_{2}} a_{j}\right\} & =\max _{j \in V_{1}} a_{j}+\max _{j \in V_{2}} a_{j}-\min \left\{\max _{j \in V_{1}} a_{j}, \max _{j \in V_{2}} a_{j}\right\} \\
& =\max _{j \in V_{1}} a_{j}+\max _{j \in V_{2}} a_{j}-\psi\left(\mathbf{w}, V_{1}, V_{2}\right)-\max _{j \in V_{1} \cap V_{2}} a_{j}
\end{aligned}
$$

which together with the nonnegativity of $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)$ establishes inequality (17). From this relation, it is easy to see that inequality (17) holds at equality if and only if $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)=0$ and that inequality (17) is strict if $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)>0$.

To finish the proof, note that $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)=0$ if $V_{1}=V_{2}$. Suppose that $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)>0$, so $V_{1} \neq V_{2}$. Observe that since $V_{1} \neq V_{2}$, at least one of them must be nonempty. Without loss of generality we assume $V_{1} \neq \emptyset$. Now, if $V_{2}=\emptyset$, then $V_{1} \cap V_{2}=\emptyset$ implying $\min \left\{\max _{j \in V_{1}} a_{j}, \max _{j \in V_{2}} a_{j}\right\}=\max _{j \in\left(V_{1} \cap V_{2}\right)} a_{j}$. This then indicates $\psi\left(\mathbf{a}, V_{1}, V_{2}\right)=0$ which is a contradiction. Hence, we have $V_{2} \neq \emptyset$ as well.

Observation 3.2 holds for any vector $\mathbf{a} \in \mathbb{R}^{m}$. In what follows, we apply it for the vectors $\mathbf{w}$ and $\mathbf{v}$, as needed.

ObSERVATION 3.3 Suppose $\rho$ is a constant satisfying $|\rho| \leq 1$. Let $V_{1}$ and $V_{2}$ be given subsets of $\Omega$. Then for any vectors $\mathbf{w}, \mathbf{v} \in \mathbb{R}^{m}$, we have

$$
\begin{align*}
& \max _{j \in\left(V_{1} \cup V_{2}\right)} w_{j}+\max _{j \in\left(V_{1} \cup V_{2}\right)} v_{j}+\rho\left(\max _{j \in\left(V_{1} \cup V_{2}\right)} w_{j}-\max _{j \in\left(V_{1} \cup V_{2}\right)} v_{j}\right) \\
& \leq  \tag{18}\\
& \max _{j \in V_{1}} w_{j}+\max _{j \in V_{1}} v_{j}+\rho\left(\max _{j \in V_{1}} w_{j}-\max _{j \in V_{1}} v_{j}\right) \\
& \quad+\max _{j \in V_{2}} w_{j}+\max _{j \in V_{2}} v_{j}+\rho\left(\max _{j \in V_{2}} w_{j}-\max _{j \in V_{2}} v_{j}\right) \\
& \quad-\max _{j \in\left(V_{1} \cap V_{2}\right)} w_{j}-\max _{j \in\left(V_{1} \cap V_{2}\right)} v_{j}-\rho\left(\max _{j \in\left(V_{1} \cap V_{2}\right)} w_{j}-\max _{j \in\left(V_{1} \cap V_{2}\right)} v_{j}\right) .
\end{align*}
$$

Inequality (18) holds at equality if and only if either $\rho=1$ and $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=0$, or $\rho=-1$ and $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)=0$, or $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=\psi\left(\mathbf{v}, V_{1}, V_{2}\right)=0$. In addition, if $|\rho|<1$ and $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)>0$ or $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)>0$, then inequality (18) is strict, and both $V_{1}$ and $V_{2}$ are nonempty, and $V_{1} \neq V_{2}$.

Proof. Recall from Observation 3.2 that $\psi\left(\mathbf{w}, V_{1}, V_{2}\right) \geq 0$ and $\psi\left(\mathbf{v}, V_{1}, V_{2}\right) \geq 0$. Then for any $|\rho| \leq 1$, we have

$$
\begin{align*}
0 \leq & (1+\rho) \psi\left(\mathbf{w}, V_{1}, V_{2}\right)+(1-\rho) \psi\left(\mathbf{v}, V_{1}, V_{2}\right)  \tag{19}\\
& =\psi\left(\mathbf{w}, V_{1}, V_{2}\right)+\psi\left(\mathbf{v}, V_{1}, V_{2}\right)+\rho\left(\psi\left(\mathbf{w}, V_{1}, V_{2}\right)-\psi\left(\mathbf{v}, V_{1}, V_{2}\right)\right)
\end{align*}
$$

Also, for any $\mathbf{a} \in \mathbb{R}^{m}$,

$$
\begin{align*}
\psi\left(\mathbf{a}, V_{1}, V_{2}\right) & =\min \left\{\max _{j \in V_{1}} a_{j}, \max _{j \in V_{2}} a_{j}\right\}-\max _{j \in\left(V_{1} \cap V_{2}\right)} a_{j} \\
& =\max _{j \in V_{1}} a_{j}+\max _{j \in V_{2}} a_{j}-\max _{j \in V_{1} \cup V_{2}} a_{j}-\max _{j \in\left(V_{1} \cap V_{2}\right)} a_{j} \tag{20}
\end{align*}
$$

By plugging in the expansion of $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)$ and $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)$ from (20) in inequality (19) and rearranging the terms, we arrive at inequality (18).

Clearly, inequality (19) holds at equality if and only if either $\rho=1$ and $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=0$, or $\rho=-1$ and $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=0$, or $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=\psi\left(\mathbf{v}, V_{1}, V_{2}\right)=0$. Also, inequality (19) holds in strict sense whenever $|\rho|<1$, and $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)>0$ or $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)>0$. Moreover, in such a case, Observation 3.2 implies $V_{1} \neq \emptyset$, $V_{2} \neq \emptyset$, and $V_{1} \neq V_{2}$.

We prove that $\operatorname{conv}(\mathcal{P})$ is obtained by the variable bounds and inequalities (9)-(11) by showing that for any nonzero cost vector $\left(c_{p}, c_{d}, \mathbf{f}\right)$, either the associated minimization problem is unbounded or we can find an inequality among inequalities (1c)-(1d), (9)-(11) and (16) that is satisfied by all of the optimal extreme point solutions corresponding to the cost vector $\left(c_{p}, c_{d}, \mathbf{f}\right)$ at equality. The only recessive direction of $\mathcal{P}$ is $(1,0,0)$ (see Proposition 3.1), thus the minimization problem over $\mathcal{P}$ is unbounded only if the cost vector $\left(c_{p}, c_{d}, \mathbf{f}\right)$ satisfies $c_{p}<0$. Consequently, we focus on the case where the minimization problem is bounded and we assume $c_{p} \geq 0$. In addition, if there exists an index $j \in \Omega$ such that $f_{j}<0$, then $z_{j}=1$ in all optimal solutions. Hence, throughout the rest of the discussion we assume that $c_{p} \geq 0$ and $f_{j} \geq 0$, for all $j \in \Omega$. Furthermore, if $c_{p}=0$, then either $c_{d} \neq 0$, or there exists an index $j \in \Omega$ such that $f_{j}>0$, because $\left(c_{p}, c_{d}, \mathbf{f}\right) \neq(0,0, \mathbf{0})$. For the former case, if $c_{d}>0$, then in all of the optimal solutions, $y_{d}=0$. Otherwise, if $c_{d}<0$, then in all of the optimal solutions, $y_{d}=u_{d}$. For the latter case, if $f_{j}>0$, for some $j \in \Omega$, then in all of the optimal solutions, $z_{j}=0$ because we can increase the value of $y_{p}$ at no cost. Hence, without loss of generality, we assume $c_{p}>0$, and to simplify notation, we rescale the cost vector as $\left(1, c_{d}, \mathbf{f}\right)$. We break the proof of Theorem 3.1 into different cases based on $c_{d}$, and examine each case separately.

We start with a few preliminaries on the structure of optimal extreme point solutions and alternative optima characterizations. Note that given a linear objective vector $\left(c_{p}, c_{d}, \mathbf{f}\right)$, we denote the cost of a given solution by $F(\bullet)$. Also, recall our convention that if $V=\emptyset$, then $\max _{j \in V} w_{j}=\max _{j \in V} v_{j}=0$.

In the next lemma, for given sets $V_{1}, V_{2} \subseteq \Omega$, we establish certain relationships between the objective function values of the solutions $A\left(V_{1}\right), A\left(V_{2}\right), A\left(V_{1} \cup V_{2}\right)$ and $A\left(V_{1} \cap V_{2}\right)$, which will then allow us to characterize when these solutions constitute alternative optima.

Lemma 3.2 Let $V_{1}, V_{2}$ be two subsets of $\Omega$. Then the following statements hold.
(i)

$$
\begin{equation*}
F\left(A\left(V_{1} \cup V_{2}\right)\right) \leq F\left(A\left(V_{1}\right)\right)+F\left(A\left(V_{2}\right)\right)-F\left(A\left(V_{1} \cap V_{2}\right)\right) \tag{21}
\end{equation*}
$$

(ii) If $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)>0$, then inequality (21) is strict, and $V_{1} \neq \emptyset, V_{2} \neq \emptyset$, and $V_{1} \neq V_{2}$. Inequality (21) holds at equality if and only if $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=0$.
(iii) If $A\left(V_{1}\right)$ and $A\left(V_{2}\right)$ are alternative optimal solutions for a given linear objective function, then both $A\left(V_{1} \cup V_{2}\right)$ and $A\left(V_{1} \cap V_{2}\right)$ are also optima and $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=0$.

Proof. Given $V_{1}, V_{2} \subseteq \Omega$, Lemma 3.1 implies $A\left(V_{1}\right), A\left(V_{2}\right), A\left(V_{1} \cap V_{2}\right)$ and $A\left(V_{1} \cup V_{2}\right)$ are all feasible.
(i) We have

$$
\begin{align*}
F\left(A\left(V_{1} \cup V_{2}\right)\right) & =\max _{j \in V_{1} \cup V_{2}} w_{j}+\sum_{j \in \Omega \backslash\left(V_{1} \cup V_{2}\right)} f_{j} \\
& \leq \max _{j \in V_{1}} w_{j}+\sum_{j \in \Omega \backslash V_{1}} f_{j}+\max _{j \in V_{2}} w_{j}+\sum_{j \in \Omega \backslash V_{2}} f_{j}-\max _{j \in\left(V_{1} \cap V_{2}\right)} w_{j}-\sum_{j \in \Omega \backslash\left(V_{1} \cap V_{2}\right)} f_{j}  \tag{22}\\
& =F\left(A\left(V_{1}\right)\right)+F\left(A\left(V_{2}\right)\right)-F\left(A\left(V_{1} \cap V_{2}\right)\right)
\end{align*}
$$

where inequality (22) follows from Observation 3.2 applied to $V_{1}$ and $V_{2}$ with $\mathbf{a}=\mathbf{w}$, and

$$
\begin{equation*}
\sum_{j \in \Omega \backslash\left(V_{1} \cup V_{2}\right)} f_{j}=\sum_{j \in \Omega \backslash V_{1}} f_{j}+\sum_{j \in \Omega \backslash V_{2}} f_{j}-\sum_{j \in \Omega \backslash\left(V_{1} \cap V_{2}\right)} f_{j} . \tag{23}
\end{equation*}
$$

(ii) If $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)>0$, then from Observation 3.2 inequality (22) is strict and $V_{1}, V_{2}$ are nonempty distinct subsets of $\Omega$. In addition, inequality (22) holds at equality if and only if $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=0$.
(iii) Now suppose that $A\left(V_{1}\right)$ and $A\left(V_{2}\right)$ are alternative optimal solutions for a given linear objective function. Because both solutions $A\left(V_{1} \cup V_{2}\right)$ and $A\left(V_{1} \cap V_{2}\right)$ are feasible, we have $F\left(A\left(V_{1} \cup V_{2}\right)\right) \geq$ $F\left(A\left(V_{1}\right)\right)$ and $F\left(A\left(V_{1} \cap V_{2}\right)\right) \geq F\left(A\left(V_{1}\right)\right)$ from the optimality of $A\left(V_{1}\right)$. Moreover, inequality (21) implies the relation

$$
\frac{F\left(A\left(V_{1} \cup V_{2}\right)\right)+F\left(A\left(V_{1} \cap V_{2}\right)\right)}{2} \leq \frac{F\left(A\left(V_{1}\right)\right)+F\left(A\left(V_{2}\right)\right)}{2}=F\left(A\left(V_{1}\right)\right)
$$

where the equation follows because both $A\left(V_{1}\right)$ and $A\left(V_{2}\right)$ are optimal. From this inequality, the optimality of both $A\left(V_{1} \cup V_{2}\right)$ and $A\left(V_{1} \cap V_{2}\right)$ follows immediately. Then the relation $F\left(A\left(V_{1} \cup\right.\right.$ $\left.\left.V_{2}\right)\right)+F\left(A\left(V_{1} \cap V_{2}\right)\right)=F\left(A\left(V_{1}\right)\right)+F\left(A\left(V_{2}\right)\right)$ implies that $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=0$ from part (ii).

Similar to Lemma 3.2, in the next lemma, for given sets $V_{1}, V_{2} \subseteq \Omega$, we establish certain relationships between the objective function values of the solutions $B\left(V_{1}\right), B\left(V_{2}\right), B\left(V_{1} \cup V_{2}\right)$ and $B\left(V_{1} \cap V_{2}\right)$, which will then allow us to characterize when these solutions constitute alternative optima.

Lemma 3.3 Let $V_{1}, V_{2}$ be two subsets of $\Omega$. Then $F\left(B\left(V_{1} \cup V_{2}\right)\right) \leq F\left(B\left(V_{1}\right)\right)+F\left(B\left(V_{2}\right)\right)-F\left(B\left(V_{1} \cap V_{2}\right)\right)$. If $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)>0$, then the inequality above is strict, and $V_{1} \neq \emptyset, V_{2} \neq \emptyset$, and $V_{1} \neq V_{2}$. The inequality above
holds at equality if and only if $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)=0$. If $B\left(V_{1}\right)$ and $B\left(V_{2}\right)$ are alternative optimal solutions for a given linear objective function, then both $B\left(V_{1} \cup V_{2}\right)$ and $B\left(V_{1} \cap V_{2}\right)$ are also optima and $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)=0$.

Proof. The proof is identical to the proof for Lemma 3.2, where we use Observation 3.2 applied to $V_{1}$ and $V_{2}$ with $\mathbf{a}=\mathbf{v}$.

Our next lemma is similar to Lemmas 3.2 and 3.3, and, for given sets $V_{1}, V_{2} \subseteq \Omega$, we establish certain relationships between the objective function values of the solutions $C\left(V_{1}\right), C\left(V_{2}\right), C\left(V_{1} \cup V_{2}\right)$ and $C\left(V_{1} \cap V_{2}\right)$, which will then allow us to characterize when these solutions constitute alternative optima.

Lemma 3.4 Let $V_{1}, V_{2}$ be two subsets of $\Omega$. Suppose $c_{p}=1$ and $\left|c_{d}\right|<1$. Then $F\left(C\left(V_{1} \cup V_{2}\right)\right) \leq$ $F\left(C\left(V_{1}\right)\right)+F\left(C\left(V_{2}\right)\right)-F\left(C\left(V_{1} \cap V_{2}\right)\right)$. If $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)>0$ or $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)>0$, then $V_{1} \neq \emptyset, V_{2} \neq \emptyset$ and $V_{1} \neq V_{2}$ and the inequality above is strict. If $C\left(V_{1}\right)$ and $C\left(V_{2}\right)$ are alternative optimal solutions for a given linear objective function, then both $C\left(V_{1} \cup V_{2}\right)$ and $C\left(V_{1} \cap V_{2}\right)$ are also optima and $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=$ $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)=0$.

Proof. Given that $V_{1}$ and $V_{2}$ are subsets of $\Omega$, from Lemma 3.1, points $C\left(V_{1}\right), C\left(V_{2}\right), C\left(V_{1} \cap V_{2}\right)$ and $C\left(V_{1} \cup V_{2}\right)$ are feasible. If $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)>0$ or $\psi\left(\mathbf{v}, V_{1}, V_{2}\right)>0$, then Observation 3.2 applied to $V_{1}$ and $V_{2}$ with $\mathbf{a}=\mathbf{w}$ or $\mathbf{a}=\mathbf{v}$ implies that $V_{1} \neq \emptyset, V_{2} \neq \emptyset$, and $V_{1} \neq V_{2}$. Moreover, we have

$$
\begin{align*}
& F( \left.C\left(V_{1} \cup V_{2}\right)\right) \\
&=\frac{\max _{j \in V_{1} \cup V_{2}} w_{j}+\max _{j \in V_{1} \cup V_{2}} v_{j}}{2}+c_{d} \frac{\max _{j \in V_{1} \cup V_{2}} w_{j}-\max _{j \in V_{1} \cup V_{2}} v_{j}}{2}+\sum_{j \in \Omega \backslash\left(V_{1} \cup V_{2}\right)} f_{j} \\
& \leq \frac{\max _{j \in V_{1}} w_{j}+\max _{j \in V_{1} v_{j}}}{2}+c_{d} \frac{\max _{j \in V_{1}} w_{j}-\max _{j \in V_{1}} v_{j}}{2}+\sum_{j \in \Omega \backslash V_{1}} f_{j} \\
&+\frac{\max _{j \in V_{2}} w_{j}+\max _{j \in V_{2}} v_{j}}{2}+c_{d} \frac{\max _{j \in V_{2}} w_{j}-\max _{j \in V_{2}} v_{j}}{2}+\sum_{j \in \Omega \backslash V_{2}} f_{j} \\
&-\left(\frac{\left.\max _{j \in\left(V_{1} \cap V_{2}\right)} w_{j}+\max _{j \in\left(V_{1} \cap V_{2}\right) v_{j}}+c_{d} \frac{\max _{j \in\left(V_{1} \cap V_{2}\right)} w_{j}-\max _{j \in\left(V_{1} \cap V_{2}\right)} v_{j}}{2}+\sum_{j \in \Omega \backslash\left(V_{1} \cap V_{2}\right)} f_{j}\right)}{2}=\right.  \tag{j}\\
& \quad F\left(C\left(V_{1}\right)\right)+F\left(C\left(V_{2}\right)\right)-F\left(C\left(V_{1} \cap V_{2}\right)\right),
\end{align*}
$$

where the inequality follows from Observation 3.3 applied to $V_{1}$ and $V_{2}$, and the relation in (23). Finally, similar to the proof of Lemma 3.2, if $C\left(V_{1}\right)$ and $C\left(V_{2}\right)$ are alternative optimal solutions for a given objective function, then both $C\left(V_{1} \cup V_{2}\right)$ and $C\left(V_{1} \cap V_{2}\right)$ are also optima and $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=\psi\left(\mathbf{v}, V_{1}, V_{2}\right)=0$.

Next, we study the form of the optimal solutions based on the structure of the objective vector. First, observe that $B(\emptyset)=\left(u_{d}, u_{d}, \mathbf{1}\right)=D+u_{d}(1,0, \mathbf{0})$ is not an extreme point, and thus it cannot be uniquely optimal. $B(\emptyset)$ can be an alternative optimal solution only when both $D$ is optimal and $c_{p}=0$ holds. Because we focus on the case of $c_{p}=1$, we do not need to consider $B(\emptyset)$ in our analysis.

Lemma 3.5 Consider a cost vector of the form $\left(1, c_{d}, \mathbf{f}\right)$ with $\mathbf{f} \geq \mathbf{0}$. Then,
(i) when $c_{d}>1$, all of the optimal solutions have the form $A(V)$ for some $V \subseteq \Omega$.
(ii) when $c_{d}=1$, all of the optimal solutions have the form $A(V)$ or $C(V)$ for some $V \subseteq \Omega$.
(iii) when $c_{d}<-1$, all of the optimal solutions have the form $D$ or $B(V)$ for some $\emptyset \neq V \subseteq \Omega$.
(iv) when $c_{d}=-1$, all of the optimal solutions have the form $D, B(V)$, or $C(V)$ for some $\emptyset \neq V \subseteq \Omega$.
(v) when $-1<c_{d}<1$, all of the optimal solutions have the form $D$ or $C(V)$ for some $V \subseteq \Omega$.

Proof. First, note that when $\max _{j \in V} w_{j}=\max _{j \in V} v_{j}$ for some $V \subseteq \Omega$, then $A(V)=C(V)$ (see Remark $3.1($ iii) ). Hence, we will consider such points as of the form $A(V)$ or $C(V)$, whichever is appropriate. Therefore, in the rest of the proof we assume that $\max _{j \in V} w_{j}>\max _{j \in V} v_{j}$ for all $\emptyset \neq V \subseteq \Omega$.
(i) Because $F(D)-F(A(\emptyset))=c_{d} u_{d}$ and $c_{d}, u_{d}>0$ holds, we have $F(A(\emptyset))<F(D)$. Then $D$ cannot be optimal. Note $A(\emptyset)=C(\emptyset)$. Consider a given $\emptyset \neq V \subseteq \Omega$. We will show that $F(A(V))<F(C(V))<F(B(V))$. Note that $F(A(V))<F(C(V))$ because

$$
\begin{aligned}
\max _{j \in V} w_{j} & =\frac{\max _{j \in V} w_{j}+\max _{j \in V} v_{j}}{2}+\left(\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}\right) \\
& <\frac{\max _{j \in V} w_{j}+\max _{j \in V} v_{j}}{2}+c_{d}\left(\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}\right) \\
& <\max _{j \in V} v_{j}+u_{d}+c_{d} u_{d}
\end{aligned}
$$

where the first inequality follows from $c_{d}>1$ and the assumption that $\max _{j \in V} w_{j}>\max _{j \in V} v_{j}$, for all $V \subseteq \Omega$, and the second inequality follows because $u_{d}>\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}$ for all $V \subseteq \Omega$ (see Remark 3.1(i)). Then for any $\emptyset \neq V \subseteq \Omega$, the first inequality establishes $F(A(V))<F(C(V))$ and the second one establishes $F(C(V))<F(B(V))$. Hence, the points of the form $B(V)$ and $C(V)$ for some $\emptyset \neq V \subseteq \Omega$ cannot be optimal for this cost vector. As a result, only the points of the form $A(V)$ for some $V \subseteq \Omega$ can be optimal when $c_{d}>1$.
(ii) Similar to the preceding case, for any $V \subseteq \Omega$, if $c_{d}=1$, then $F(A(V))=F(C(V))<F(B(V))$, and $F(A(\emptyset))<F(D)$. The result then follows.
(iii) Because $u_{d}>0$ and $c_{d}<-1$, we have $F(D)-F(A(\emptyset))=c_{d} u_{d}<0$. Hence, $F(D)<F(A(\emptyset))$.

Consider $\emptyset \neq V \subseteq \Omega$. Next, we will show that $F(B(V))<F(C(V))<F(A(V))$. Note $F(B(V))<F(C(V))$ holds because

$$
\begin{align*}
& F(B(V))-F(C(V)) \\
& \quad=\max _{j \in V} v_{j}+u_{d}+c_{d} u_{d}-\left(\frac{\max _{j \in V} w_{j}+\max _{j \in V} v_{j}}{2}\right)-c_{d}\left(\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}\right) \\
& \quad=\left(1+c_{d}\right)\left(u_{d}-\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}\right)  \tag{24}\\
& \quad<0
\end{align*}
$$

where the strict inequality follows from $c_{d}<-1$ and the assumption $u_{d}>\frac{1}{2}\left(\max _{j \in V} w_{j}-\right.$ $\max _{j \in V} v_{j}$ ) for all $V \subseteq \Omega$. Also, for $\emptyset \neq V \subseteq \Omega$, we have $F(C(V))<F(A(V))$, because

$$
\begin{align*}
F(C(V))-F(A(V)) & =\left(\frac{\max _{j \in V} w_{j}+\max _{j \in V} v_{j}}{2}\right)+c_{d}\left(\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}\right)-\max _{j \in \Omega} w_{j} \\
& =\left(c_{d}-1\right)\left(\frac{\max _{j \in V} w_{j}-\max _{j \in V} v_{j}}{2}\right) \tag{25}
\end{align*}
$$

$$
<0
$$

where the strict inequality follows from $c_{d}<-1$ and $\max _{j \in V} w_{j}>\max _{j \in V} v_{j}$. Hence, we have $F(B(V))<F(C(V))<F(A(V))$, and $F(D)<F(A(\emptyset))$, which proves that if $c_{d}<-1$, then the optimal solutions are of the form $D$, and $B(V)$, for some $\emptyset \neq V \subset \Omega$.
(iv) Similar to the preceding case, for any $\emptyset \neq V \subseteq \Omega$, because $c_{d}=-1$, we have $F(B(V))=$ $F(C(V))<F(A(V))$, and $F(D)<F(A(\emptyset))$. The result then follows.
(v) In this case, from equations (24) and (25), it can be seen that $F(C(V))<F(B(V))$ and $F(C(V))<F(A(V))$ for any $\emptyset \neq V \subseteq \Omega$. Also, by noting $A(\emptyset)=C(\emptyset)$, we conclude the optimal solutions are the points of the form $D$ or $C(V)$ for some $V \subseteq \Omega$.

We now show that we can find an inequality among inequalities (9)-(11) that is satisfied at equality by all optimal extreme point solutions in $\mathcal{P}$ for the given objective function vector of the form $\left(1, c_{d}, \mathbf{f}\right)$. Throughout the rest of this section, let $\mathcal{O}:=\left\{o_{1}, o_{2}, \ldots, o_{p_{1}}\right\}$ be the set of optimal solutions for the given objective vector $\left(1, c_{d}, \mathbf{f}\right)$. In addition, let $o_{i}:=\left(y_{p}^{i}, y_{d}^{i}, \mathbf{z}^{i}\right)$, for all $o_{i} \in \mathcal{O}, i \in\left[p_{1}\right]$, be an optimal solution. For all $o_{i} \in \mathcal{O}, i \in\left[p_{1}\right]$, set $V_{i}:=\left\{j \in \Omega: z_{j}^{i}=0\right\}$. Furthermore, for $V_{i} \neq \emptyset, i \in\left[p_{1}\right]$, we define $j_{i}^{*}=\arg \max \left\{w_{j} \mid z_{j}^{i}=0, j \in \Omega\right\}$, and $\bar{j}_{i}=\arg \max \left\{v_{j} \mid z_{j}^{i}=0, j \in \Omega\right\}$, for all $i \in\left[p_{1}\right]$. Before we proceed, we make an observation on points on the same face.

Remark $3.2(i)$ Given any $\emptyset \neq V \subseteq \Omega$, an inequality of form (9) is tight for the point $A(V)$ if and only if the same inequality is tight for the point $C(V)$. To see this, note that for any $V \subseteq \Omega$, $y_{p}+y_{d}=\max _{j \in V} w_{j}$ for both $A(V)$ and $C(V)$.
(ii) Given any $\emptyset \neq V \subseteq \Omega$, an inequality of form (10) is tight for the point $B(V)$ if and only if the same inequality is tight for the point $C(V)$. To see this, note that for any $V \subseteq \Omega, y_{p}-y_{d}=\max _{j \in V} v_{j}$ for both $B(V)$ and $C(V)$.

We next show that given a subset of points of a desired form, we can construct a mixing inequality (9) that is satisfied at equality at all these points. Recall, from Remark 3.2 (i), that if a point of form $A(V)$ is on the face defined by (9), then so is $C(V)$ for some $V \subseteq \Omega$.

Lemma 3.6 Suppose $\hat{p} \geq 2$ and $\widehat{\mathcal{O}}:=\left\{\hat{o}_{1}, \ldots, \hat{o}_{\hat{p}}\right\}$ is a subset of points $\hat{o}_{i}$ of form $A\left(V_{i}\right)$ or $C\left(V_{i}\right)$ for some $V_{i} \subseteq \Omega$ such that for all $\hat{o}_{i}, \hat{o}_{j} \in \widehat{\mathcal{O}}$, we have both $\psi\left(\mathbf{w}, V_{i}, V_{j}\right)=0$ and there exists $\hat{o}_{\kappa} \in \widehat{\mathcal{O}}$ satisfying $\hat{o}_{\kappa} \in\left\{A\left(V_{i} \cap V_{j}\right), C\left(V_{i} \cap V_{j}\right)\right\}$. Then there exists a mixing inequality (9) corresponding to the sequence $S=\left\{s_{1} \rightarrow \ldots \rightarrow s_{\eta}\right\}$, where $\left\{s_{1}, \ldots, s_{\eta}\right\}:=\left\{\alpha_{1}\right\} \cup\left\{j_{1}^{*}, j_{2}^{*}, \ldots, j_{\hat{p}}^{*}\right\}$, $s_{1}=\alpha_{1}$, and for all $j \in[\eta]$, $w_{s_{j}} \geq w_{s_{j+1}}$ with $w_{s_{n+1}}=0$ defined for convenience, that is satisfied at equality at all solutions in $\widehat{\mathcal{O}}$.

Proof. To prove our claim, first, observe that if $A(\emptyset)=C(\emptyset) \in \widehat{\mathcal{O}}$, then substituting the point $A(\emptyset)$ into inequality (9) defined by the sequence $S$ in the premise of the lemma, the left-hand side becomes $\sum_{j=1}^{\eta}\left(w_{s_{j}}-w_{s_{j+1}}\right)=w_{s_{1}}=w_{\alpha_{1}}$, which proves that inequality (9) defined by $S$ is tight at $A(\emptyset)=C(\emptyset) \in \widehat{\mathcal{O}}$.

Next consider any solution $\hat{o}_{i}=A\left(V_{i}\right) \in \widehat{\mathcal{O}}$ or $\hat{o}_{i}=C\left(V_{i}\right) \in \widehat{\mathcal{O}}$ with $V_{i} \neq \emptyset$ and $i \in[\hat{p}]$. From the definitions of $A\left(V_{i}\right)$ and $C\left(V_{i}\right)$, we have $y_{p}^{i}+y_{d}^{i}=w_{j_{i}^{*}}$ (recall the definition of $j_{i}^{*}$ ) and $z_{k}^{i}=1$ for all $k \in \Omega$
such that $w_{k}>w_{j_{i}^{*}}$ (from inequality (1a) in the original constraint set). Also, by definition of $S, j_{i}^{*}=s_{k_{i}}$ for some $k_{i} \in[\eta]$, and we have $w_{s_{j}} \geq w_{s_{k_{i}}}$ for $j \in\left[k_{i}-1\right]$; hence, $z_{s_{j}}^{i}=1$ for all $j \in\left[k_{i}-1\right]$ such that $w_{s_{j}}>w_{s_{k_{i}}}$. Then $\sum_{j=1}^{k_{i}}\left(w_{s_{j}}-w_{s_{j+1}}\right) z_{s_{j}}^{i}=w_{\alpha_{1}}-w_{s_{k_{i}}}$ where the equality holds because $z_{s_{k_{i}}}^{i}=0, s_{1}=\alpha_{1}$ and for all $j \in\left[k_{i}-1\right]$ we have $z_{s_{j}}^{i}=1$ if $w_{s_{j}}>w_{s_{k_{i}}}$. Substituting this term and the relation $y_{p}^{i}+y_{d}^{i}=w_{j_{i}^{*}}=w_{s_{k_{i}}}$ in inequality (9) leads to the equivalent inequality given by

$$
\begin{equation*}
w_{s_{k_{i}}}+w_{\alpha_{1}}-w_{s_{k_{i}}}+\sum_{j=k_{i}+1}^{\eta}\left(w_{s_{j}}-w_{s_{j+1}}\right) z_{s_{j}}^{i} \geq w_{\alpha_{1}} \tag{26}
\end{equation*}
$$

Suppose, for contradiction, that $\hat{o}_{i}$ does not satisfy inequality (9) at equality for this choice of $S$. Then, from (26), we see that we must have $\sum_{j=k_{i}+1}^{\eta}\left(w_{s_{j}}-w_{s_{j+1}}\right) z_{s_{j}}^{i}>0$. In other words, there exists $s_{j^{\prime}} \in S$ for some $j^{\prime} \in[\eta] \backslash\left[k_{i}\right]$ with both $z_{s_{j^{\prime}}}^{i}=1$ (i.e., $\left.s_{j^{\prime}} \notin V_{i}\right)$ and $w_{s_{j^{\prime}}}-w_{s_{j^{\prime}+1}}>0$. This along with Observation 2.1 implies that $w_{s_{j^{\prime}}}>0$. Moreover, from $j^{\prime} \in[\eta] \backslash\left[k_{i}\right], s_{k_{i}}=j_{i}^{*}$ and the definition of the sequence $S$, we deduce $w_{s_{j^{\prime}}} \leq w_{s_{k_{i}}}=w_{j_{i}^{*}}$.

Because $s_{j^{\prime}} \in S \backslash V_{i}$, there exists another point, say $\hat{o}_{\ell}=A\left(V_{\ell}\right) \in \widehat{\mathcal{O}}$ or $\hat{o}_{\ell}=C\left(V_{\ell}\right) \in \widehat{\mathcal{O}}$, such that $s_{j^{\prime}}=\arg \max \left\{w_{j} \mid z_{j}^{\ell}=0, j \in \Omega\right\}=j_{\ell}^{*}$. Hence, $s_{j^{\prime}} \in V_{\ell} \backslash V_{i}$. Thus,

$$
\min \left\{\max _{j \in V_{i}} w_{j}, \max _{j \in V_{\ell}} w_{j}\right\}=\min \left\{w_{j_{i}^{*}}, w_{s_{j^{\prime}}}\right\}=w_{s_{j^{\prime}}}=\max _{j \in V_{\ell}} w_{j}>\max _{j \in\left(V_{i} \cap V_{\ell}\right)} w_{j}
$$

where in the equations we have used respectively the definitions of $j_{i}^{*}$ and $j_{\ell}^{*}$ along with $s_{j^{\prime}}=j_{\ell}^{*}$, and the fact that $w_{s_{j^{\prime}}} \leq w_{j_{i}^{*}}$. Whenever $V_{i} \cap V_{\ell}=\emptyset$, the strict inequality above follows from $w_{s_{j^{\prime}}}>0$ and our convention that $\max _{j \in V} w_{j}=0$ for $V=\emptyset$. Whenever $V_{i} \cap V_{\ell} \neq \emptyset$, recall that if $\hat{o}_{i} \in\left\{A\left(V_{i}\right), C\left(V_{i}\right)\right\}$ is in $\widehat{\mathcal{O}}$ and $\hat{o}_{\ell} \in\left\{A\left(V_{\ell}\right), C\left(V_{\ell}\right)\right\}$ is in $\widehat{\mathcal{O}}$, then from the premise of the lemma, we have $V_{\kappa}:=V_{i} \cap V_{\ell}$ such that $\hat{o}_{\kappa} \in\left\{A\left(V_{\kappa}\right), C\left(V_{\kappa}\right)\right\}$ is also in $\widehat{\mathcal{O}}$ which implies that the strict inequality above follows from $j_{\ell}^{*}=s_{j^{\prime}} \notin V_{i} \cap V_{\ell}$, hence $j_{\kappa}^{*}=s_{k_{\kappa}}$ for some $\eta \geq k_{\kappa} \geq j^{\prime}+1$ and that $w_{s_{j^{\prime}}}>w_{s_{j^{\prime}+1}} \geq w_{j_{\kappa}^{*}}$. Consequently, we reach a contradiction because this inequality implies $\psi\left(\mathbf{w}, V_{i}, V_{\ell}\right)>0$ contradicting the premise of the lemma. As a result, $s_{j^{\prime}}$ cannot exist, i.e., $z_{s_{j}}^{i}=0$ for all $j=k_{i}+1, \ldots, \eta$ in inequality (26). Hence inequality (9) for this choice of $S$ must be tight at any solution $\hat{o}_{i} \in \widehat{\mathcal{O}}$ satisfying the premise of the lemma.

In the next lemma, we show that given a subset of points of a desired form, we can construct a mixing inequality (10) that is satisfied at equality at all these points. Recall, from Remark 3.2 (ii), that if a point of form $B(V)$ is on the face defined by (9), then so is $C(V)$ for some $V \subseteq \Omega$.

Lemma 3.7 Suppose $\hat{p} \geq 2$ and $\widehat{\mathcal{O}}:=\left\{\hat{o}_{1}, \ldots, \hat{o}_{\hat{p}}\right\}$ is a subset of points $\hat{o}_{i}$ of form $D, B\left(V_{i}\right)$ or $C\left(V_{i}\right)$ for some $\emptyset \neq V_{i} \subseteq \Omega$ such that for all $\hat{o}_{i}, \hat{o}_{j} \in \widehat{\mathcal{O}}$, we have both $\psi\left(\mathbf{v}, V_{i}, V_{j}\right)=0$ and there exists $\hat{o}_{\kappa} \in \widehat{\mathcal{O}}$ satisfying $\hat{o}_{\kappa} \in\left\{B\left(V_{i} \cap V_{j}\right), C\left(V_{i} \cap V_{j}\right)\right\}$. Then there exists a mixing inequality (10) corresponding to the sequence $T=\left\{t_{1} \rightarrow \ldots \rightarrow t_{\rho}\right\}$, where $\left\{t_{1}, \ldots, t_{\rho}\right\}:=\left\{\beta_{1}\right\} \cup\left\{\bar{j}_{1}, \bar{j}_{2}, \ldots, \bar{j}_{\hat{p}}\right\}, t_{1}=\beta_{1}$, and for all $j \in[\rho]$, $v_{t_{j}} \geq v_{t_{j+1}}$ with $v_{t_{\rho+1}}=-u_{d}$ defined for convenience, that is satisfied at equality at all solutions in $\widehat{\mathcal{O}}$.

Proof. The proof of Lemma 3.7 is similar to the proof of Lemma 3.6. We provide the details in Appendix C for completeness.

Finally, we show that given a subset of points of a desired form, we can construct a generalized mixing inequality (11) that is satisfied at equality at all these points, which are optimal solutions if $c_{d}=0$.

Lemma 3.8 Suppose $c_{d}=0, p_{1}>2$, and $\mathcal{O}$ is a set of optimal solutions of form $D$ and $C(V)$ for some
$V \subseteq \Omega$ satisfying $\mathcal{O} \supset\{D, C(\emptyset)\}$. Then there exists a sequence $\Pi \subseteq \Omega$ such that the generalized mixing inequality (11) corresponding to the sequence $\Pi$ is satisfied at equality at all optimal solutions in $\mathcal{O}$.

Proof. Given $D, C(\emptyset) \in \mathcal{O}$, we let $o_{p_{1}}=D$, and set $p_{1}^{\prime}=p_{1}-1$. Because $\mathcal{O} \neq\{D, C(\emptyset)\}$, there exists $i \in\left[p_{1}^{\prime}\right]$ and $o_{i} \in \mathcal{O}$ such that $o_{i}=C\left(V_{i}\right)$ with $V_{i} \neq \emptyset$. In this case, we claim that there always exists an inequality (11) that is tight for all optimal solutions in $\mathcal{O}$. To do this, we first need to define a sequence $\Pi$.
(a) We first claim that there exists a maximal nested subsequence $V_{1} \supset V_{2} \supset \cdots \supset V_{q}=\emptyset$, where $q \leq p_{1}^{\prime}$ corresponding to the optimal solutions $o_{1}=C\left(V_{1}\right), o_{2}=C\left(V_{2}\right), \ldots, o_{q}=C\left(V_{q}\right)$, such that $y_{p}^{1} \geq y_{p}^{2} \geq \cdots \geq y_{p}^{q}$ and $\left|V_{1}\right|>\left|V_{2}\right|>\cdots>\left|V_{q}\right|$. This subsequence is maximal in that there does not exist an optimal solution $o_{j}=C\left(V_{j}\right) \in \mathcal{O}$ for $q<j \leq p_{1}^{\prime}$ where $V_{i-1} \subset V_{j} \subset V_{i}$ for some $2 \leq i \leq q$. In addition, $V_{1}=\cup_{i=1}^{p_{1}^{\prime}} V_{i}$ and $V_{q}=\cap_{i=1}^{p_{1}^{\prime}} V_{i}=\emptyset$. Let us now argue that such a maximal nested subsequence exists. Recall, from Lemma 3.4 that if $C\left(V_{i}\right)$ and $C\left(V_{j}\right)$ are alternative optima for some $i \neq j \in\left[p_{1}^{\prime}\right]$, then so are $C\left(V_{i} \cup V_{j}\right)$ and $C\left(V_{i} \cap V_{j}\right)$. Hence, if $V_{i} \not \subset V_{j}$, then $V_{i} \cup V_{j} \supset V_{i} \supset V_{i} \cap V_{j}$ or $V_{i} \cup V_{j} \supset V_{j} \supset V_{i} \cap V_{j}$ form two partial nested subsequences based on the pair $V_{i}$ and $V_{j}$ only. (If $V_{i} \subset V_{j}$, then $V_{i} \cup V_{j}=V_{j}$ and $V_{i} \cap V_{j}=V_{i}$, and the partial subsequence is $V_{j} \supset V_{i}$.) Repeating this argument for all pairs, we see that we must have a maximal nested subsequence $V_{1} \supset V_{2} \supset \cdots \supset V_{q}=\emptyset$, with $V_{1}=\cup_{i=1}^{p_{1}^{\prime}} V_{i}$ and $V_{q}=\cap_{i=1}^{p_{1}^{\prime}} V_{i}=\emptyset$.
(b) Now, we show how to construct a sequence $\Pi$ that results in an inequality (11) that is tight at the optimal solutions $o_{1}, \ldots, o_{q}$. During this construction, we also consider the properties of the coefficients of the $z$ variables in the inequality being constructed. To this end, let $\theta_{\pi_{j}}$ represent the coefficient of the variable $z_{\pi_{j}}$ in inequality (11), i.e., $\theta_{\pi_{j}}=\left(w_{\pi_{j}}-\bar{w}_{\Pi, j}\right)_{+}+\left(v_{\Pi, j}-\bar{v}_{\Pi, j}\right)_{+}$. For convenience, we set $\theta_{j}=0$ for all $j \in \Omega \backslash \Pi$. In addition, for notational convenience, we define $j_{q}^{*}:=j_{q-1}^{*}$ and $\bar{j}_{q}:=\bar{j}_{q-1}$ because $V_{q}=\emptyset$. Consider the subsequence constructed in (a). We will only consider $j_{i}^{*}$ and $\bar{j}_{i}$ for $i \in[q-1]$ for inclusion in $\Pi$. The index $k \in[q]$ will consider the optimal solutions starting from $o_{1}$ until $o_{q}$. The index $\ell$ will track the items being added to the sequence $\Pi$. The construction of $\Pi$ works such that when we consider $o_{k}$ for $k>1$, the items $j_{i}^{*}$ and $\bar{j}_{i}$ for $i \in[k-1]$ will already be in $\Pi$ and they will precede $j_{k}^{*}$ and $\bar{j}_{k}$, unless $j_{k}^{*}=j_{i}^{*}$ or $\bar{j}_{k}=\bar{j}_{i}$ for some $i \in[k-1]$. We initialize by letting $\ell, k=1$. While $k<q$, consider $V_{k}$ and its corresponding $j_{k}^{*}$ and $\bar{j}_{k}$. There are four cases to consider, which we describe next.

- If $j_{k}^{*}=j_{k+1}^{*}$ and $\bar{j}_{k}=\bar{j}_{k+1}$. In this case we do not add an element to $\Pi$.
- If $j_{k}^{*} \neq j_{k+1}^{*}$ and $\bar{j}_{k}=\bar{j}_{k+1}$, then let $\pi_{\ell}=j_{k}^{*}$. Note that $\theta_{\pi_{\ell}}=w_{\pi_{\ell}}-\max _{j \in V_{k+1}} w_{j}+\left(v_{\pi_{\ell}}-\right.$ $\left.\max _{j \in V_{k+1}} v_{j}\right)_{+}=w_{j_{k}^{*}}-w_{j_{k+1}^{*}} \geq 0$, because only the items $j_{i}^{*}$ and $\bar{j}_{i}$ for $i \in[q]$ are included in the sequence $\Pi$, and $V_{k+1} \supset V_{k+2} \supset \cdots \supset V_{q}$, so $v_{\pi_{\ell}}=v_{j_{k}^{*}} \leq v_{\bar{j}_{k}}=v_{\bar{j}_{k+1}}$ implying $\left(v_{j_{k}^{*}}-v_{\bar{j}_{k+1}}\right)_{+}=0$. In addition, $\sum_{j \in V_{k} \backslash V_{k+1}} \theta_{j}=\theta_{j_{k}^{*}}+\sum_{j \in V_{k} \backslash\left(V_{k+1} \cup\left\{j_{k}^{*}\right\}\right)} \theta_{j}=\theta_{j_{k}^{*}}=\theta_{\pi_{\ell}}=$ $w_{j_{k}^{*}}-w_{j_{k+1}^{*}}=w_{j_{k}^{*}}-w_{j_{k+1}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}}$, where the second equation follows because any item $j \in V_{k} \backslash\left(V_{k+1} \cup\left\{j_{k}^{*}\right\}\right)$ is not included in the construction of $\Pi$ (due to the nested nature of the subsets $V$, if $j \notin V_{k+1}$ then it is not in $V_{i}$, for $k+1<i \leq q$ ), hence $\theta_{j}=0$ for such $j$, and the last equation follows from $\bar{j}_{k}=\bar{j}_{k+1}$. Let $\ell \leftarrow \ell+1$.
- Similarly, if $j_{k}^{*}=j_{k+1}^{*}$ and $\bar{j}_{k} \neq \bar{j}_{k+1}$, then let $\pi_{\ell}=\bar{j}_{k}$. Note that $\theta_{\pi_{\ell}}=v_{\pi_{\ell}}-\max _{j \in V_{k+1}} v_{j}=$ $v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}} \geq 0$. In addition, $\sum_{j \in V_{k} \backslash V_{k+1}} \theta_{j}=w_{j_{k}^{*}}-w_{j_{k+1}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}}+\sum_{j \in V_{k} \backslash\left(V_{k+1} \cup\left\{\bar{j}_{k}\right\}\right)} \theta_{j}=$ $w_{j_{k}^{*}}-w_{j_{k+1}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}}$, because any item $j \in V_{k} \backslash\left(V_{k+1} \cup\left\{\bar{j}_{k}\right\}\right)$ is not included in the construction of $\Pi$ (due to the nested nature of the subsets $V$, if $j \notin V_{k+1}$ then it is not in $V_{i}$, for $k+1<i \leq q)$, hence $\theta_{j}=0$ for such $j$. Let $\ell \leftarrow \ell+1$.
- Finally, consider the case of $j_{k}^{*} \neq j_{k+1}^{*}, \bar{j}_{k} \neq \bar{j}_{k+1}$. First, suppose $j_{k}^{*} \neq \bar{j}_{k}$. In this case, let $\pi_{\ell}=j_{k}^{*}$ and $\pi_{\ell+1}=\bar{j}_{k}$. Now observe that $\theta_{\pi_{\ell}}=\left(w_{j_{k}^{*}}-\max _{j \in V_{k+1} \cup\left\{\bar{j}_{k}\right\}} w_{j}\right)_{+}+\left(v_{j_{k}^{*}}-\right.$ $\left.\max _{j \in V_{k+1} \cup\left\{\bar{j}_{k}\right\}} v_{j}\right)_{+}=w_{j_{k}^{*}}-\max _{j \in V_{k+1} \cup\left\{\bar{j}_{k}\right\}} w_{j}$, because $v_{j_{k}^{*}} \leq v_{\bar{j}_{k}}$, by definition of $\bar{j}_{k}$. In addition, $\theta_{\pi_{\ell+1}}=\left(w_{\bar{j}_{k}}-\max _{j \in V_{k+1}} w_{j}\right)_{+}+\left(v_{\bar{j}_{k}}-\max _{j \in V_{k+1}} v_{j}\right)_{+}=\left(w_{\bar{j}_{k}}-\max _{j \in V_{k+1}} w_{j}\right)_{+}+v_{\bar{j}_{k}}-$ $\max _{j \in V_{k+1}} v_{j}$. Now consider $\theta_{\pi_{\ell}}+\theta_{\pi_{\ell+1}}=\left(w_{j_{k}^{*}}-\max _{j \in V_{k+1} \cup\left\{\bar{j}_{k}\right\}} w_{j}\right)+\left(w_{\bar{j}_{k}}-\max _{j \in V_{k+1}} w_{j}\right)_{+}+$ $v_{\bar{j}_{k}}-\max _{j \in V_{k+1}} v_{j}$. There are two cases to consider. If $w_{\bar{j}_{k}}>\max _{j \in V_{k+1}} w_{j}$ or if $w_{\bar{j}_{k}} \leq$ $\max _{j \in V_{k+1}} w_{j}$. However, in either case, $\theta_{\pi_{\ell}}+\theta_{\pi_{\ell+1}}=w_{j_{k}^{*}}-w_{j_{k+1}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}}$. In addition, $\sum_{j \in V_{k} \backslash V_{k+1}} \theta_{j}=w_{j_{k}^{*}}-w_{j_{k+1}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}}+\sum_{j \in V_{k} \backslash\left(V_{k+1} \cup\left\{j_{j_{k}^{*}} \bar{j}_{k}\right\}\right)} \theta_{j}=w_{j_{k}^{*}}-w_{j_{k+1}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}}$, because any item $j \in V_{k} \backslash\left(V_{k+1} \cup\left\{j_{k}^{*}, \bar{j}_{k}\right\}\right)$ is not included in the construction of $\Pi$ (due to the nested nature of the subsets $V$, if $j \notin V_{k+1}$ then it is not in $V_{i}, k+1<i \leq q$ ), hence $\theta_{j}=0$ for such $j$. Let $\ell \leftarrow \ell+2$. (If $j_{k}^{*}=\bar{j}_{k}$, then we let $\pi_{\ell}=j_{k}^{*}=\bar{j}_{k}$ and $\ell \leftarrow \ell+1$. The remaining arguments follow similarly.)

Let $k \leftarrow k+1$, and repeat this process until $k=q-1$. Note also that due to our construction, $\sum_{j \in V_{k} \backslash V_{h}} \theta_{j}=w_{j_{k}^{*}}-w_{j_{h}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{h}}$ for any $1 \leq k<h \leq q$.

Next we show that the resulting sequence $\Pi$ yields an inequality (11) that is tight at the optimal solutions $o_{1}, \ldots, o_{q}$. First, note $D$ and $C(\emptyset)=C\left(V_{q}\right)$ make inequality (11) generated by this $\Pi$ tight because the left-hand side of inequality (11) is $\bar{w}_{\Pi, 0}+\bar{v}_{\Pi, 0}$, which equals to the right-hand side of inequality (11). From our construction, $j_{1}^{*}$ and $\bar{j}_{1}$ are guaranteed to be in the sequence $\Pi$, hence $\bar{w}_{\Pi, 0}=w_{j_{1}^{*}}$ and $\bar{v}_{\Pi, 0}=v_{\bar{j}_{1}}$. As a result, the right-hand side of inequality (11) for this choice of $\Pi$ is $w_{j_{1}^{*}}+v_{\bar{j}_{1}}$. We will show the tightness of this inequality by induction on the optimal solution index $k$. First, consider $k=1$. Let us consider the left-hand side of inequality (11) for this choice of $\pi$ evaluated at $o_{1}$. Note that $y_{p}^{1}=\frac{1}{2}\left(w_{j_{1}^{*}}+v_{\bar{j}_{1}}\right)$ and $z_{j}^{1}=0$ for all $j \in \Pi$. Hence, the inequality is tight at $o_{1}$. Now suppose that the inequality is tight at $o_{k}$, then we will show that it is also tight at $o_{k+1}$ for $k \in[q-2]$ (recall that the tightness of this inequality is already shown for $o_{k}=C\left(V_{q}\right)$ ). Note that, comparing the inequality (11) evaluated at $o_{k+1}$ to its evaluation at $o_{k}$, the decrease in the $2 y_{p}$ term in the left-hand side of the inequality (11) is $w_{j_{k}^{*}}-w_{j_{k+1}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}}$, and the increase in the $\sum_{j \in \Pi} \theta_{j} z_{j}$ term is $\sum_{j \in V_{k} \backslash V_{k+1}} \theta_{j}=w_{j_{k}^{*}}-w_{j_{k+1}^{*}}+v_{\bar{j}_{k}}-v_{\bar{j}_{k+1}}$. Hence, the inequality is tight at $o_{k+1}$ as well. Furthermore, for $1 \leq i<k<q$, we have $F\left(o_{i}\right)=\frac{1}{2}\left(w_{j_{i}^{*}}+v_{\bar{j}_{i}}\right)+\sum_{j \in \Omega \backslash V_{i}} f_{j}=$ $\frac{1}{2}\left(w_{j_{k}^{*}}+v_{\bar{j}_{k}}\right)+\sum_{j \in \Omega \backslash V_{k}} f_{j}=F\left(o_{k}\right)$, hence $\sum_{j \in V_{i} \backslash V_{k}} f_{j}=\frac{1}{2}\left(w_{j_{i}^{*}}+v_{\bar{j}_{i}}-\left(w_{j_{k}^{*}}+v_{\bar{j}_{k}}\right)\right)=\frac{1}{2} \sum_{j \in V_{i} \backslash V_{k}} \theta_{j}$. Also, $F\left(o_{q}\right)=F(C(\emptyset))=\sum_{j \in \Omega} f_{j}$.
(c) Finally, we show that for this choice of $\Pi$, inequality (11) is also tight at the optimal solutions $o_{q+1}, \ldots, o_{p_{1}^{\prime}}$. Consider $o_{i}$ for $q<i \leq p_{1}^{\prime}$. Because $o_{i}$ does not belong to the maximal nested subsequence chosen in (a), we must have $V_{\nu_{1}} \supset V_{i} \not \supset V_{\nu_{1}+1}$ for some $\nu_{1} \in[q-2]$, because $V_{q}=\emptyset$. Note that $\nu_{1}$ exists because we have $V_{1} \supset V_{j}$ for all $j \in\left[p_{1}^{\prime}\right]$. Recall that $C\left(V_{i}\right), C\left(V_{j}\right) \in \mathcal{O}$ implies $C\left(V_{i} \cap V_{j}\right), C\left(V_{i} \cup V_{j}\right) \in \mathcal{O}$. Thus, $V_{\nu_{1}}=V_{i} \cup V_{\nu_{1}+1}$, and there exists $V_{\nu_{2}}=V_{i} \cap V_{\nu_{1}+1}$, where $\nu_{1}+1<\nu_{2} \leq q$. Note that $\nu_{2}$ exists because we have $V_{q} \subseteq V_{j}$ for all $j \in\left[p_{1}^{\prime}\right]$. Moreover, $F\left(o_{\nu_{1}}\right)=\frac{1}{2}\left(w_{j_{\nu_{1}}^{*}}+v_{\bar{j}_{\nu_{1}}}\right)+\sum_{j \in \Omega \backslash V_{\nu_{1}}} f_{j}=\frac{1}{2}\left(w_{j_{i}^{*}}+v_{\bar{j}_{i}}\right)+\sum_{j \in \Omega \backslash V_{i}} f_{j}=F\left(o_{i}\right)$. Hence, we must have $\sum_{j \in V_{\nu_{1}} \backslash V_{i}} f_{j}=\frac{1}{2}\left(w_{j_{\nu_{1}}^{*}}+v_{\bar{j}_{\nu_{1}}}-\left(w_{j_{i}^{*}}+v_{\bar{j}_{i}}\right)\right)$. We have shown that $o_{\nu_{1}}, o_{\nu_{1}+1}$ and $o_{\nu_{2}}$ satisfy inequality (11) at equality. Comparing the left-hand side of inequality (11) evaluated at $o_{\nu_{1}}$ and $o_{i}$ we see that the decrease in the $2 y_{p}$ term in the left-hand side of the inequality is $w_{j_{\nu_{1}}}-w_{j_{i}^{*}}+v_{\bar{j}_{\nu_{1}}}-v_{\bar{j}_{i}}$, and the increase in the $\sum_{j \in \Pi} \theta_{j} z_{j}$ term is $\sum_{j \in V_{\nu_{1}} \backslash V_{i}} \theta_{j}$. Then the difference between the left-hand
side of inequality (11) evaluated at $o_{\nu_{1}}$ and $o_{i}$ is

$$
\begin{aligned}
w_{j_{\nu_{1}}^{*}}-w_{j_{i}^{*}}+v_{\bar{j}_{\nu_{1}}}-v_{\bar{j}_{i}}-\sum_{j \in V_{\nu_{1}} \backslash V_{i}} \theta_{j} & =w_{j_{\nu_{1}}^{*}}-w_{j_{i}^{*}}+v_{\bar{j}_{\nu_{1}}}-v_{\bar{j}_{i}}-\sum_{j \in V_{\nu_{1}+1} \backslash V_{\nu_{2}}} \theta_{j} \\
& =w_{j_{\nu_{1}}^{*}}-w_{j_{i}^{*}}+v_{\bar{j}_{\nu_{1}}}-v_{\bar{j}_{i}}-2 \sum_{j \in V_{\nu_{1}+1} \backslash V_{\nu_{2}}} f_{j} \\
& =w_{j_{\nu_{1}}^{*}}-w_{j_{i}^{*}}+v_{\bar{j}_{\nu_{1}}}-v_{\bar{j}_{i}}-2 \sum_{j \in V_{\nu_{1}} \backslash V_{i}} f_{j} \\
& =2\left(F\left(o_{\nu_{1}}\right)-F\left(o_{i}\right)\right)=0,
\end{aligned}
$$

where the first and third equations follow from $V_{\nu_{1}} \backslash V_{i}=V_{\nu_{1}+1} \backslash V_{\nu_{2}}$, and the second equation from the relation between the coefficients $\theta$ and $f$. As a result, the left-hand side of inequality (11) evaluated at $o_{\nu_{1}}$ is equal to that evaluated at $o_{i}$. Because we have shown that inequality (11) is tight at $o_{\nu_{1}}$, it must be tight at $o_{i}$ as well.

We are now ready to give the proof of Theorem 3.1.
Proof. [Proof of Theorem 3.1] From Proposition 3.1, we observe that $\mathcal{O}$ is composed of points of form $A(\emptyset)=C(\emptyset), D$, and $A(V), B(V), C(V)$ for some $\emptyset \neq V \subset \Omega$.

First, we show that if $p_{1}=1$, then we can find an inequality (9) or (10) that is tight for this single point. If $o_{1}=A(\emptyset)$ (or $o_{1}=D$ ), then clearly every mixing inequality (9) ((10)) for any nonempty sequence $S(T)$ is satisfied at equality by this point. Otherwise, if $o_{1}=A(V)$ for some $\emptyset \neq V \subseteq \Omega$, then we consider two cases. If $w_{j_{1}^{*}}=w_{\alpha_{1}}$, then we let $S=\left\{j_{1}^{*}\right\}$. In this case, because $z_{j_{1}^{*}}=0$, the left-hand side of inequality (9) generated by this choice of $S$ is $w_{j_{1}^{*}}=w_{\alpha_{1}}$, implying that inequality (9) is tight at the point $o_{1}$. Otherwise, if $w_{j_{1}^{*}}<w_{\alpha_{1}}$, then we have $S=\left\{\alpha_{1}, j_{1}^{*}\right\}$ and $z_{\alpha_{1}}^{1}=1$. In this case, the left-hand side of inequality (9) for this choice of $S$ is $w_{j_{1}^{*}}+\left(w_{\alpha_{1}}-w_{j_{1}^{*}}\right) z_{\alpha_{1}}=w_{\alpha_{1}}$, which also implies that inequality (9) is tight at the point $o_{1}$. Otherwise, if $o_{1}=B(V)$ or $o_{1}=C(V)$, for some $\emptyset \neq V \subseteq \Omega$, then we can find a mixing inequality (10) using a procedure similar to the preceding discussion.

Next, if $p_{1} \geq 2$, then we break the proof into several cases based on the objective coefficient $c_{d}$ :
(i) Suppose $c_{d}>0$. In this case, for any two points $o_{i}, o_{j} \in \mathcal{O}$ for $i, j \in\left[p_{1}\right]$, we first claim that both $o_{i}, o_{j}$ are of the form $A(V)$ or $C(V)$ for some $V \subseteq \Omega$, such that we have both $\psi\left(\mathbf{w}, V_{i}, V_{j}\right)=0$ and there exists $o_{k} \in \mathcal{O}$ satisfying $o_{k} \in\left\{A\left(V_{i} \cap V_{j}\right), C\left(V_{i} \cap V_{j}\right)\right\}$.

- Suppose $c_{d}>1$. From Lemma 3.5(i), we deduce that only points of the form $A(V)$ for some $V \subseteq \Omega$ can be optimal for this type of a cost vector. For any two points $o_{i}=A\left(V_{i}\right), o_{j}=A\left(V_{j}\right)$ such that $o_{i}, o_{j} \in \mathcal{O}$, Lemma 3.2(iii) implies that both $A\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$ and $\psi\left(\mathbf{w}, V_{i}, V_{j}\right)=0$.
- Suppose that $c_{d}=1$. From Lemma 3.5(ii), we deduce that only points of the form $A(V)$ or $C(V)$ for some $V \subseteq \Omega$ can be optimal for this type of a cost vector. Given that $c_{d}=1$, for any $o_{i} \in \mathcal{O}, i \in\left[p_{1}\right], A\left(V_{i}\right)$ is an optimal solution if and only if $C\left(V_{i}\right)$ is an optimal solution because the sum $y_{p}+y_{d}$ is the same for the solutions $C(V)$ and $A(V)$ corresponding to the same set $V$. Then for any two points $o_{1} \in\left\{A\left(V_{1}\right), C\left(V_{1}\right)\right\}, o_{2} \in\left\{A\left(V_{2}\right), C\left(V_{2}\right)\right\}$ such that $o_{1}, o_{2} \in \mathcal{O}$, Lemma 3.2(iii) implies that $\psi\left(\mathbf{w}, V_{1}, V_{2}\right)=0$ and $A\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$ and $C\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$.
- If $0<c_{d}<1$, then $F(D)>F(C(\emptyset))$. Hence, from Lemma 3.5(v), the points of the form
$C(V)$ for some $V \subseteq \Omega$ can be optimal, but $D \notin \mathcal{O}$. Moreover, for any $C\left(V_{i}\right), C\left(V_{j}\right) \in \mathcal{O}$ for $V_{i}, V_{j} \subseteq \Omega, V_{i} \neq V_{j}$, from Lemma 3.4 we have $\psi\left(\mathbf{w}, V_{i}, V_{j}\right)=0$ and $C\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$.
Then Lemma 3.6 shows that we can always find a sequence $S$ such that the mixing inequality (9) corresponding to $S$ is tight for all solutions in $\mathcal{O}$.
(ii) Suppose $c_{d}=0$. From Lemma 3.5(v), we deduce that only points of the form $C(V)$ for some $V \subseteq \Omega$ and $D$ can be optimal for this type of a cost vector. Recall from Lemma 3.4, we have for any $C\left(V_{i}\right), C\left(V_{j}\right) \in \mathcal{O}$ for $V_{i}, V_{j} \subseteq \Omega, V_{i} \neq V_{j}$ that $\psi\left(\mathbf{w}, V_{i}, V_{j}\right)=0$ and $C\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$. Consequently, observe that if $D \notin \mathcal{O}$, then all points in $\mathcal{O}$ are of the form $C(V)$ for some $V \subseteq \Omega$. In such a case, Lemma 3.6 shows that we can always find a sequence $S$ such that the mixing inequality (9) corresponding to $S$ is tight for all solutions in $\mathcal{O}$. Therefore, without loss of generality we can assume that $D \in \mathcal{O}$.
Now note that $F(D)=F(C(\emptyset))$ because $c_{d}=0$. Therefore, we have both $D, C(\emptyset) \in \mathcal{O}$.
- When $p_{1}=2$, since $D, C(\emptyset) \in \mathcal{O}$, we have $\mathcal{O}=\{D, C(\emptyset)\}$. In this case, the generalized mixing inequality (11) corresponding to $\Pi=\left\{\alpha_{1} \rightarrow \beta_{1}\right\}$ is tight for all solutions in $\mathcal{O}$.
- When $p_{1}>2$, we have $\mathcal{O} \supset\{D, C(\emptyset)\}$. Then there exists $o_{i}=C\left(V_{i}\right) \in \mathcal{O}, i \in\left[p_{1}\right]$ for some $\emptyset \neq V_{i} \subseteq \Omega$. In this case, Lemma 3.8 shows that we can always find a sequence $\Pi \subseteq \Omega$ such that the generalized mixing inequality (11) corresponding to $\Pi$ is tight for all solutions in $\mathcal{O}$.
(iii) Suppose $c_{d}<0$. In this case, for any two points $o_{i}, o_{j} \in \mathcal{O}$, we first claim that both $o_{i}, o_{j}$ are of the form $D, B(V)$ or $C(V)$ for some $\emptyset \neq V \subseteq \Omega$. Moreover, we claim that for any $o_{i} \in\left\{B\left(V_{i}\right), C\left(V_{i}\right)\right\}$ and $o_{j} \in\left\{B\left(V_{j}\right), C\left(V_{j}\right)\right\}$ with $\emptyset \neq V_{i}, V_{j} \subseteq \Omega$, we have both $\psi\left(\mathbf{v}, V_{i}, V_{j}\right)=0$ and there exists $o_{k} \in \mathcal{O}$ satisfying $o_{k} \in\left\{B\left(V_{i} \cap V_{j}\right), C\left(V_{i} \cap V_{j}\right)\right\}$.
- Suppose $c_{d}<-1$. From Lemma 3.5(iii), we deduce that only points of form $D$ or $B(V)$ for some $\emptyset \neq V \subseteq \Omega$ can be optimal for this type of a cost vector. For any two points $o_{i}=B\left(V_{i}\right)$, $o_{j}=B\left(V_{j}\right)$ such that $o_{i}, o_{j} \in \mathcal{O}$, Lemma 3.3 implies that $\psi\left(\mathbf{v}, V_{i}, V_{j}\right)=0$ and $B\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$. Because $B\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$ and $B(\emptyset) \notin \mathcal{O}$, we deduce $V_{i} \cap V_{j} \neq \emptyset$.
- Suppose that $c_{d}=-1$. From Lemma 3.5(iv), we deduce that only points of the form $D$, $B(V)$ or $C(V)$ for some $\emptyset \neq V \subseteq \Omega$ can be optimal for this type of a cost vector. Given that $c_{d}=-1$, for any $o_{i} \in \mathcal{O}, i \in\left[p_{1}\right], B\left(V_{i}\right) \in \mathcal{O}$ if and only if $\left.C\left(V_{i}\right)\right) \in \mathcal{O}$ because the term $y_{p}-y_{d}$ is the same for the solutions $C(V)$ and $B(V)$ corresponding to the same set $V$. Then for any two points $o_{i} \in\left\{B\left(V_{i}\right), C\left(V_{i}\right)\right\}, o_{j} \in\left\{B\left(V_{j}\right), C\left(V_{j}\right)\right\}$ such that $o_{i}, o_{j} \in \mathcal{O}$, we deduce $C\left(V_{i}\right), C\left(V_{j}\right) \in \mathcal{O}$ and then Lemma 3.4 implies that $\psi\left(\mathbf{v}, V_{i}, V_{j}\right)=0$ and $C\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$. Because $C\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$ and $C(\emptyset) \notin \mathcal{O}$, we conclude that $V_{i} \cap V_{j} \neq \emptyset$, and $B\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$.
- If $-1<c_{d}<0$, then $F(D)<F(C(\emptyset))$. Hence, from Lemma 3.5(v), only the points of the form $D$ or $C(V)$ for some $\emptyset \neq V \subseteq \Omega$ can be optimal. Moreover, for any $C\left(V_{i}\right), C\left(V_{j}\right) \in \mathcal{O}$ for $\emptyset \neq V_{i}, V_{j} \subseteq \Omega$, Lemma 3.4 implies $\psi\left(\mathbf{v}, V_{i}, V_{j}\right)=0$ and $C\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$. Once again, because $C\left(V_{i} \cap V_{j}\right) \in \mathcal{O}$ and $C(\emptyset) \notin \mathcal{O}$, we deduce that $V_{i} \cap V_{j} \neq \emptyset$.
Then Lemma 3.7 shows that we can always find a sequence $T$ such that the mixing inequality (10) corresponding to $T$ is tight for all solutions in $\mathcal{O}$.

4. Separation of Inequalities (11) In this section, we discuss exact and heuristic separation approaches for inequality (11). Let ( $\left.\hat{y}_{p}, \hat{y}_{d}, \hat{\mathbf{z}}\right)$ be a fractional solution. In order to find the most violated
inequality (11), we need to find a sequence $\Pi=\left\{\pi_{1} \rightarrow \pi_{2} \rightarrow \cdots \rightarrow \pi_{\tau}\right\}$ that minimizes the value of the term $\sum_{j=1}^{\tau}\left(\left(w_{\pi_{j}}-\bar{w}_{\Pi, j}\right)_{+}+\left(v_{\pi_{j}}-\bar{v}_{\Pi, j}\right)_{+}\right) \hat{z}_{\pi_{j}}$. Throughout this section, this value is interpreted as cost.
4.1 An Exact Separation Approach In this section, we give a polynomial-time dynamic programming algorithm to separate inequality (11) exactly. Without loss of generality, we assume that the sequence $\Pi$ has length $m$. Here, we only consider the case where $\alpha_{1} \in \Pi$ and $\beta_{1} \in \Pi$, because otherwise the resulting inequality can be strengthened by including $\alpha_{1}$ and $\beta_{1}$.

In our dynamic programming algorithm, the states are given by $\left(i, j, \bar{W}_{i-1}, \bar{V}_{i-1}\right)$ for $i, j \in \Omega=$ [ $m$ ], $\bar{W}_{i-1} \geq w_{j}$ and $\bar{V}_{i-1} \geq v_{j}$, where $\bar{W}_{i-1}$ and $\bar{V}_{i-1}$ represent the values of $\bar{w}_{\Pi, i-1}$ and $\bar{v}_{\Pi, i-1}$ for the constructed sequence $\Pi$, respectively. Note that for any $k \in[m]$, the eligible values of $\bar{W}_{k}$ and $\bar{V}_{k}$ are from the entries of the vectors $\mathbf{w}$ and $\mathbf{v}$, respectively. The state function is $\bar{G}_{i}\left(j, \bar{W}_{i-1}, \bar{V}_{i-1}\right)$, which is defined as the minimum cost of the subsequence $\pi_{i} \rightarrow \pi_{i+1} \rightarrow \cdots \rightarrow \pi_{m}$, where item $j$ is the first item in this subsequence (i.e., $\pi_{i}=j$ ), $\max \left\{w_{\pi_{j}}: i \leq j \leq m\right\}=\bar{w}_{\Pi, i-1}=\bar{W}_{i-1}$, and $\max \left\{v_{\pi_{j}}: i \leq j \leq m\right\}=\bar{v}_{\Pi, i-1}=\bar{V}_{i-1}$. Note that there are $\mathrm{O}\left(m^{4}\right)$ many possible states $\left(i, j, \bar{W}_{i-1}, \bar{V}_{i-1}\right)$, because $i, j \in[m]$ and $\bar{W}_{i-1}=w_{k}$ for some $k \in \Omega$ and $\bar{V}_{i-1}=v_{k^{\prime}}$ for some $k^{\prime} \in \Omega$.

Next, the boundary condition is defined as:

$$
\bar{G}_{m}\left(j, \bar{W}_{m-1}, \bar{V}_{m-1}\right)= \begin{cases}\left(w_{j}+v_{j}\right) \hat{z}_{j}, & \text { if } \bar{W}_{m-1}=w_{j}, \text { and } \bar{V}_{m-1}=v_{j} \\ +\infty, & \text { if } \bar{W}_{m-1}>w_{j}, \text { or } \bar{V}_{m-1}>v_{j}\end{cases}
$$

where the state $\bar{G}_{m}\left(j, \bar{W}_{m-1}, \bar{V}_{m-1}\right)$, in which $\bar{W}_{m-1}>w_{j}$ or $\bar{V}_{m-1}>v_{j}$ is infeasible, because if item $j=\pi_{m}$, then we must have $\bar{W}_{m-1}=w_{j}$ and $\bar{V}_{m-1}=v_{j}$. The optimal solution is then given by $\min \left\{\bar{G}_{1}\left(\alpha_{1}, w_{\alpha_{1}}, v_{\beta_{1}}\right), \bar{G}_{1}\left(\beta_{1}, w_{\alpha_{1}}, v_{\beta_{1}}\right)\right\}$, because $\alpha_{1}$ and $\beta_{1}$ are in $\Pi$, and without loss of generality, we have $w_{\pi_{1}}=w_{\alpha_{1}}$ or $v_{\pi_{1}}=v_{\beta_{1}}$.

Finally, we give the backward transition function

$$
\begin{aligned}
& \bar{G}_{i}\left(j, \bar{W}_{i-1}, \bar{V}_{i-1}\right)= \\
& \begin{cases}\min _{j^{\prime} \in \Omega}\left\{\bar{G}_{i+1}\left(j^{\prime}, \bar{W}_{i-1}, \bar{V}_{i-1}\right)\right\}, & \text { if } \bar{W}_{i-1}>w_{j}, \text { and } \bar{V}_{i-1}>v_{j}, \\
\min _{j^{\prime} \in \Omega, \bar{W}_{i} \leq w_{j}, \bar{V}_{i} \leq v_{j}}\left\{\bar{G}_{i+1}\left(j^{\prime}, \bar{W}_{i}, \bar{V}_{i}\right)+\left(w_{j}+v_{j}-\bar{W}_{i}-\bar{V}_{i}\right) \hat{z}_{j}\right\}, & \text { if } \bar{W}_{i-1}=w_{j}, \text { and } \bar{V}_{i-1}=v_{j}, \\
\min _{j^{\prime} \in \Omega, \bar{W}_{i} \leq w_{j}}\left\{\bar{G}_{i+1}\left(j^{\prime}, \bar{W}_{i}, \bar{V}_{i-1}\right)+\left(w_{j}-\bar{W}_{i}\right) \hat{z}_{j}\right\}, & \text { if } \bar{W}_{i-1}=w_{j}, \text { and } \bar{V}_{i-1}>v_{j}, \\
\min _{j^{\prime} \in \Omega, \bar{V}_{i} \leq v_{j}}\left\{\bar{G}_{i+1}\left(j^{\prime}, \bar{W}_{i-1}, \bar{V}_{i}\right)+\left(v_{j}-\bar{V}_{i}\right) \hat{z}_{j}\right\}, & \text { if } \bar{W}_{i-1}>w_{j}, \text { and } \bar{V}_{i-1}=v_{j} .\end{cases}
\end{aligned}
$$

The running time of executing the transition function is $\mathrm{O}\left(\mathrm{m}^{3}\right)$, so the total running time of this dynamic programming algorithm is $O\left(m^{7}\right)$.
4.2 Heuristic Separation Approaches Given the inefficiency of the exact separation algorithm in Section 4.1, in this section we discuss simple heuristic separation approaches for (11) with complexity $O(m \log m)$. The underlying idea for these heuristics is that instead of trying to minimize the overall term $\sum_{j=1}^{\tau}\left(\left(w_{\pi_{j}}-\bar{w}_{\Pi, j}\right)_{+}+\left(v_{\pi_{j}}-\bar{v}_{\Pi, j}\right)_{+}\right) \hat{z}_{\pi_{j}}$, we can aim to minimize the partial sum terms for involving only $w_{j}$ 's or only $v_{j}$ 's.

Suppose that the polynomial-time separation algorithm in [5] is applied to find the mixing sequences
$S^{*}=\left\{s_{1}=\alpha_{1} \rightarrow s_{2} \rightarrow \cdots \rightarrow s_{\eta}\right\}$ and $T^{*}=\left\{t_{1}=\beta_{1} \rightarrow t-2 \rightarrow \cdots \rightarrow t_{\rho}\right\}$ that maximize the violation of inequalities (9) and (10), respectively. Next, based on the sequences $S^{*}$ and $T^{*}$, as a heuristic separation procedure for (11), we generate the sequence $\Pi:=t_{1} \rightarrow t_{2} \rightarrow \cdots \rightarrow t_{\rho} \rightarrow s_{1} \rightarrow s_{2} \rightarrow \cdots \rightarrow s_{\eta}$, where we append sequence $S^{*}$ after the sequence $T^{*}$. Then clearly $R[\Pi] \supseteq S^{*}$ because $s_{1}=\alpha_{1}$ and by definition of the sequences $\alpha$ and $S^{*}$, we have $w_{s_{1}}=w_{\alpha_{1}} \geq w_{t_{i}}$ for all $i \in[\rho]$ as well as $w_{s_{1}} \geq w_{s_{i}}$ for all $i \in[\eta]$ which implies $\bar{w}_{\Pi, 1}=w_{\alpha_{1}}$. In fact, we have $R[\Pi]=S^{*}$ whenever the values of $w_{j}$ are distinct because then we would have $w_{s_{1}}=w_{\alpha_{1}}>w_{t_{i}}$ for all $i \in[\rho]$. Therefore, the sequence $\Pi$ generated by this procedure minimizes the partial summation term $\sum_{j=1}^{\tau}\left(w_{\pi_{j}}-\bar{w}_{\Pi, j}\right)_{+} \hat{z}_{\pi_{j}}$ in (11). Besides, the inequality (11) generated by this choice of $\Pi$ is different from inequality (9) for $S^{*}$ because $G[\Pi] \neq \emptyset$ (note $\beta_{1}=t_{1} \in G[\Pi]$ and $\left.s_{\eta} \in G[\Pi]\right)$ and the right hand side values of the two inequalities will differ whenever $\mathbf{v}>\mathbf{0}$.

Similarly, an alternative heuristic separation for (11) is given by generating a sequence $\Pi$ where we append $T^{*}$ after $S^{*}$, then the resulting sequence $\Pi$ minimizes the partial summation term $\sum_{j=1}^{\tau}\left(v_{\pi_{j}}-\bar{v}_{\Pi, j}\right)_{+} \hat{z}_{\pi_{j}}$, because $G[\Pi] \supseteq T^{*}$ (and whenever the values of $v_{j}$ are distinct, $G[\Pi]=T^{*}$ ).
5. Preliminary Numerical Study and Future Directions In this section, we study the computational performance of the proposed inequality (11) against adding only mixing inequalities (9) and (10) on randomly generated test instances. Our test instances are deterministic equivalents of chanceconstrained programs taking the form $\min \left\{\boldsymbol{\xi}^{\top} \mathbf{x}:(8 \mathrm{a})-(8 \mathrm{~b}),(6 \mathrm{~b})-(6 \mathrm{c}), \mathbf{x} \geq \mathbf{0}, y_{p}=\sum_{i=1}^{5} p_{i} x_{i}, y_{d}=\right.$ $\left.\sum_{i=1}^{5} d_{i} x_{i}, 0 \leq y_{d} \leq u_{d}\right\}$. We generate different classes of problems with varying scenario sizes by selecting $m=k \cdot 1000$ where $k \in[4]$, and $\epsilon \in\{0.1,0.15,0.2\}$. For each problem class, we generate three instances and report the averages. We assume that each scenario is equally likely. For $i \in[5]$, we generate $p_{i}$ and $d_{i}$ from uniform distribution $U[0,1]$, and $\xi_{i}$ from $U[1,2]$. In addition, for all $j \in \Omega, q_{j}$ is generated as $\max \left\{q_{j}^{\prime}, 0\right\}$, where $q_{j}^{\prime}$ follows the normal distribution $N(40,10)$, and $h_{j}=\min \left\{q_{j}, h_{j}^{\prime}\right\}$, where $h_{j}^{\prime}$ follows $N(20,10)$. Furthermore, $u_{d}$ is taken as $\max _{j \in \Omega}\left\{h_{j}+q_{j}\right\}$. This data generation scheme ensures that Assumptions A1, A2, and A3 are satisfied. Our test instances are available in an Online Supplement at http://faculty.washington.edu/simge/IntMix0S.zip.

All runs are executed on a Windows 7 with $2.27 \mathrm{GHZ} \operatorname{Intel}(\mathrm{R}) \mathrm{Core}(\mathrm{TM}) \mathrm{i} 3 \mathrm{CPU}$ and 2.0 GB RAM. We implemented our algorithms using C programming language, with Microsoft Visual Studio 2008 and CPLEX 12.4 in its default setting. A time limit of one hour is used for each problem instance.

In our computational study, we separate and add inequalities (9)-(11) only at the root node using the user cut callback function of CPLEX. In particular, at each fractional solution ( $\left.\hat{\mathbf{x}}, \hat{y}_{p}, \hat{y}_{d}, \hat{\mathbf{z}}\right)$ at the root node, we add at most one violated inequality of each type (9), (10) and (11), in this order, and re-solve the linear programming relaxation until either there are no further violated cuts from the given cut class or a predetermined cut limit is reached. We apply the polynomial-time separation algorithm from [2] to find the mixing sequences $S^{*}=\left\{s_{1}=\alpha_{1} \rightarrow s_{2} \rightarrow \cdots \rightarrow s_{\eta}\right\}$ and $T^{*}=\left\{t_{1}=\beta_{1} \rightarrow t-2 \rightarrow \cdots \rightarrow t_{\rho}\right\}$ that maximize the violation of inequalities (9) and (10), respectively. The exact separation algorithm presented in Section 4.1 is inefficient. Hence, we use some of the heuristic separation ideas presented in Section 4.2. In particular, we use the heuristic that constructs $\Pi$ by appending sequence $S^{*}$ after the sequence $T^{*}$. In our preliminary tests, the alternative heuristic of appending $T^{*}$ after $S^{*}$ did not provide significant improvements in the computational performance. While our focus in this paper is not on finding the most effective heuristic to separate inequality (11), we observe that our heuristic strikes a good balance between efficiency of cut generation and effectiveness in improving the integrality gaps and computational times.

In our preliminary numerical tests, we observe that a significant amount of time was being spent at the root node without too much gap improvement after a certain number of cuts are added. Thus, in our computational study, we imposed a limit on the number of cuts added at the root node. In particular, the number of mixing inequalities (9), (10) and new inequalities (11) that can be added is limited to $m \times \gamma$ for each class of inequalities, where we take $\gamma \in\{0.1,0.2\}$ e.g., for instances with $m=4000$ and $\gamma=0.1$, the cut limit is set to 400 for each class of inequalities. In our experiments, the cut limits for mixing inequalities (9) and (10) were hit in every instance for both settings for $\gamma$. This was not the case for inequalities (11).

Table 2: Effectiveness of inequalities (11) on random two-sided chance-constrained problem instances.

| Instances |  | DEP \& Mix. Ineq. $(\gamma=0.1)$ |  |  | DEP \& Mix. Ineq. $(\gamma=0.2)$ |  |  | DEP \& Mix. Ineq. \& New Ineq. ( $\gamma=0.1$ ) |  |  |  |

Table 2 summarizes our computational results. In Table 2, the section "DEP \& Mix. Ineq." reports the results of using mixing inequalities (9) and (10) only, where the cuts limits of both type of mixing inequalities are set to $m \times \gamma$ for $\gamma=0.1$ and 0.2 , and the section "DEP \& Mix. Ineq. (9), (10) \& New Ineq." reports where both mixing inequalities and the new inequalities (11) are utilized. The column "Time" reports the average solution time in seconds for the instances that are solved to optimality within the time limit. Whenever all instances are not solved to optimality within the time limit, we report two additional statistics in parentheses (\#, \%). The first number in the parentheses is the number of instances that are solved to optimality within the time limit, and the second one is the average percentage final gap for the instances that terminate due to the time limit. The column "R.Gap" reports the root node gap for the instances after adding the violated inequalities. Furthermore, the column "Nodes" displays the average number of branch-and-bound nodes explored during the process. Finally, the column "Cut" in the section "DEP \& Mix. Ineq. \& New Ineq." reports the average number of inequalities (11) that are added in addition to the $m \times \gamma$ mixing inequalities (9) and (10).

First, comparing the results of the settings "DEP \& Mix. Ineq." with $\gamma=0.1$ and $\gamma=0.2$, we see the diminishing returns of adding more mixing inequalities. This observation forms the basis for establishing cut limits. We observe that the setting with $\gamma=0.1$ provides better results in general. Hence, we set the cut limit as $m \times 0.1$ for the setting "DEP \& Mix. Ineq. \& New Ineq.". Table 2 indicates the new inequality class (11) is computationally effective: the solution time, ending gap, root node gap and number of branch-and-bound (B\&B) nodes generated are generally better for the option with the new inequality (11) than the option without the inequality (11). In particular, the improvements in the overall solution times and the number of B\&B nodes are quite significant. Besides, the column "Cut" shows that the proposed inequalities are useful in terms of cutting off the fractional solution. On the contrary, if we do not add the proposed inequalities (11) and add more mixing inequalities (9) and (10) instead, i.e., compare the sections "DEP \&
Mix. Ineq." for $\gamma=0.2$ and "DEP \& Mix. Ineq. \& New Ineq.", then the computational performance for $\gamma=0.2$ setting is still worse, both in terms of solution time (always) and average root gap (mostly).

In conclusion, not only do the proposed inequalities have desirable theoretical properties, namely that they are convex-hull defining for the set $\mathcal{P}$ for which they are derived, but they are also effective in practice where $\mathcal{P}$ appears as a substructure. Several interesting questions are left for future studies: study of an intersection of mixing sets with general coefficients on multiple shared continuous variables, strengthening of the proposed inequalities in the presence of cardinality/knapsack constraints for chance-constrained applications, and lifting the assumption on the nonnegativity i.e., Assumption A3, of the data defining the particular generalization of the intersection of mixing set $\mathcal{P}$.

Appendix A. Proof of Proposition 3.4 Proof. We first establish the necessity of the condition $w_{s_{1}}=w_{\alpha_{1}}$ for inequality (9) to be a facet. Suppose $w_{s_{1}}<w_{\alpha_{1}}$. Note that inequality (9) given for $S^{\prime}=\left\{\alpha_{1} \rightarrow s_{1} \rightarrow s_{2} \rightarrow \cdots \rightarrow s_{\eta}\right\}$ is simply

$$
y_{p}+y_{d}+\sum_{j=1}^{\eta}\left(w_{s_{j}}-w_{s_{j+1}}\right) z_{s_{j}} \geq w_{s_{1}}+\left(w_{\alpha_{1}}-w_{s_{1}}\right)\left(1-z_{\alpha_{1}}\right)
$$

This inequality is stronger than the original inequality (9) given for $S=\left\{s_{1} \rightarrow s_{2} \rightarrow \cdots \rightarrow s_{\eta}\right\}$ because $\left(w_{\alpha_{1}}-w_{s_{1}}\right)\left(1-z_{\alpha_{1}}\right) \geq 0$. Hence, this establishes the necessity of condition $w_{s_{1}}=w_{\alpha_{1}}$. The argument for the necessity of condition $v_{t_{1}}=v_{\beta_{1}}$ for inequality (10) to be a facet is identical.

To see that inequality (9) is facet defining if $w_{s_{1}}=w_{\alpha_{1}}$, first, for all $j \in \Omega \backslash S$, we consider the points $\left(w_{\alpha_{1}}, 0, \mathbf{e}_{j}\right)$. These points are feasible (see the proof of Proposition 3.3). In addition, these points satisfy inequality (9) at equality and are affinely independent. Next, for all $j \in[\eta]$, we consider the points $A\left(\cup_{i=j}^{\eta} s_{i}\right)=\left(w_{s_{j}}, 0, \sum_{i \in \Omega \backslash\left(\cup_{i=j}^{\eta} s_{i}\right)} \mathbf{e}_{s_{i}}\right)$. The feasibility of these points follow from Lemma 3.1. In addition, these points satisfy inequality (9) at equality and are affinely independent. Finally, we consider the feasible points $A(\emptyset)$ and $C(\Omega)$, which are affinely independent from all other points. In addition, $A(\emptyset)$ and $C(\Omega)$ satisfy inequality (9) at equality. Hence, we obtain $m+2$ affinely independent points that are feasible and satisfy inequality (9) at equality. This proves that inequality (9) is facet-defining for $\operatorname{conv}(\mathcal{P})$.

The proof for inequality (10) to be facet defining when $v_{t_{1}}=v_{\beta_{1}}$ is similar. In this case, we consider the points $D, C(\Omega), C(\Omega \backslash\{j\})$, for all $j \in \Omega \backslash T$, and $B\left(\cup_{i=j}^{\rho} t_{i}\right)$, for all $j \in[\rho]$ These points are feasible from Lemma 3.1 and are also affinely independent.

Appendix B. Proof of Proposition 3.5 Proof. If $w_{r_{1}}<w_{\alpha_{1}}$, then we can attach $\alpha_{1}$ at the beginning of the sequence $\Pi$ to obtain another valid inequality of form (11) (or equivalently (12))

$$
2 y_{p}+\sum_{j=1}^{\tau_{R}}\left(w_{r_{j}}-w_{r_{j+1}}\right) z_{r_{j}}+\sum_{j=1}^{\tau_{G}}\left(v_{g_{j}}-v_{g_{j+1}}\right) z_{g_{j}} \geq w_{r_{1}}+v_{g_{1}}+\left(w_{\alpha_{1}}-w_{r_{1}}\right)\left(1-z_{\alpha_{1}}\right)
$$

The resulting inequality is at least as strong as the original inequality because $w_{\alpha_{1}}>w_{r_{1}}$ and $1-z_{\alpha_{1}} \geq 0$. Similarly, if $v_{g_{1}}<v_{\beta_{1}}$, then we can attach $\beta_{1}$ at the beginning of the sequence $\Pi$ to obtain another inequality that is at least as strong as the original inequality. This shows the necessity of the facet conditions.

To see the sufficiency, first consider the feasible points $C(\emptyset)$ and $D$ (see Lemma 3.1 for their feasibility). These points satisfy inequality (11) at equality. Next, we consider the feasible point $C(\Omega)$, which satisfies inequality (11) at equality. Now, consider the points $\left(\frac{w_{\alpha_{1}}+v_{\beta_{1}}}{2}, \frac{w_{\alpha_{1}}-v_{\beta_{1}}}{2}, \mathbf{e}_{j}\right)$, for all $j \in \Omega \backslash \Pi$. For each $j \in \Omega \backslash \Pi$, using Observation 3.1(i) and the feasibility of the point $C(\Omega)=\left(\frac{w_{\alpha_{1}}+v_{\beta_{1}}}{2}, \frac{w_{\alpha_{1}}-v_{\beta_{1}}}{2}, \mathbf{0}\right)$, we conclude that these points are also feasible. Since $j \notin \Pi$, these points satisfy (11) at equality as well. Note that the points considered thus far are affinely independent.

Next, for all $j \in[\tau] \backslash\{1\}$ such that $\pi_{j} \in \Pi$, if $w_{\pi_{j}}<\bar{w}_{\Pi, j}$ and $v_{\pi_{j}}<\bar{v}_{\Pi, j}$, then we consider the point $\left(\frac{w_{\alpha_{1}}+v_{\beta_{1}}}{2}, \frac{w_{\alpha_{1}}-v_{\beta_{1}}}{2}, \mathbf{e}_{\pi_{j}}\right)$. For each such $j$, the feasibility of the associated point follows from the feasibility of $C(\Omega)$ and Observation 3.1(i). In addition, this point also satisfies inequality (11) at equality, because $\left(w_{\pi_{j}}-\bar{w}_{\Pi, j}\right)_{+}=\left(v_{\pi_{j}}-\bar{v}_{\Pi, j}\right)_{+}=0$, so the left-hand side of inequality (11), after substituting this point, becomes $w_{\alpha_{1}}+v_{\beta_{1}}$. Otherwise, if $w_{\pi_{j}} \geq \bar{w}_{\Pi, j}$ or $v_{\pi_{j}} \geq \bar{v}_{\Pi, j}$ for some $j \in[\tau] \backslash\{1\}$, then we consider the following feasible point $C\left(\Pi \backslash\left(\cup_{i=1}^{j-1}\left\{\pi_{i}\right\}\right)\right)=\left(\frac{\bar{w}_{\Pi, j-1}+\bar{v}_{\Pi, j-1}}{2}, \frac{\bar{w}_{\Pi, j-1}-\bar{v}_{\Pi, j-1}}{2}, \sum_{i=1}^{j-1} \mathbf{e}_{\pi_{i}}+\sum_{i \in(\Omega \backslash \Pi)} \mathbf{e}_{i}\right)$. Note also

$$
\sum_{i=1}^{j-1}\left(\left(w_{\pi_{i}}-\bar{w}_{\Pi, i}\right)_{+}\right)+\bar{w}_{\Pi, j-1}=\max _{\ell \in[\tau]} w_{\pi_{\ell}}=w_{\alpha_{1}},
$$

and

$$
\sum_{i=1}^{j-1}\left(\left(v_{\pi_{i}}-\bar{v}_{\Pi, i}\right)_{+}\right)+\bar{v}_{\Pi, j-1}=\max _{\ell \in[\tau]} v_{\pi_{\ell}}=v_{\beta_{1}}
$$

because $\alpha_{1} \in \Pi$ and $\beta_{1} \in \Pi$. Thus, the point $C\left(\Pi \backslash\left(\cup_{i=1}^{j-1}\left\{\pi_{i}\right\}\right)\right)$ satisfies inequality (11) at equality as well. Also, these points are affinely independent from the points listed earlier. Hence, in total, we obtain $m+2$ affinely independent feasible points that satisfy inequality (11) at equality. This completes the proof.

Appendix C. Proof of Lemma 3.7 Proof. To prove our claim, first, observe that if $D \in \widehat{\mathcal{O}}$, then substituting the point $D$ into inequality (10) defined by the sequence $T$ as defined in the premise of the lemma, the left-hand side becomes $-u_{d}+\sum_{j=1}^{\rho}\left(v_{t_{j}}-v_{t_{j+1}}\right)=v_{t_{1}}=v_{\beta_{1}}$ (recall $v_{t_{\rho+1}}$ in (10)), which proves that inequality (10) defined by $T$ is tight at $D \in \widehat{\mathcal{O}}$.

Next consider any solution $\hat{o}_{i}=B\left(V_{i}\right) \in \widehat{\mathcal{O}}$ or $\hat{o}_{i}=C\left(V_{i}\right) \in \widehat{\mathcal{O}}$ with $V_{i} \neq \emptyset$ and $i \in[\hat{p}]$. From the definitions of $B\left(V_{i}\right)$ and $C\left(V_{i}\right)$, we have $y_{p}^{i}-y_{d}^{i}=v_{\bar{j}_{i}}$ (recall the definition of $\bar{j}_{i}$ ) and $z_{k}^{i}=1$ for all $k \in \Omega$ such that $v_{k}>v_{\bar{j}_{i}}$ (from inequality (1b) in the original constraint set). Also, by definition of $T, \bar{j}_{i}=t_{k_{i}}$ for some $k_{i} \in[\rho]$, and we have $v_{t_{j}} \geq v_{t_{k_{i}}}$ for $j \in\left[k_{i}-1\right]$; hence, $z_{t_{j}}^{i}=1$ for all $j \in\left[k_{i}-1\right]$ such that $v_{t_{j}}>v_{t_{k_{i}}}$. Then $\sum_{j=1}^{k_{i}}\left(v_{t_{j}}-v_{t_{j+1}}\right) z_{t_{j}}^{i}=v_{\beta_{1}}-v_{t_{k_{i}}}$ where the equality holds because $z_{t_{k_{i}}}^{i}=0, t_{1}=\beta_{1}$ and for $j \in\left[k_{i}-1\right]$ we have $z_{t_{j}}^{i}=1$ if $v_{t_{j}}>v_{t_{k_{i}}}$. Substituting this term and the relation $y_{p}^{i}-y_{d}^{i}=v_{\bar{j}_{i}}=v_{t_{k_{i}}}$ in inequality (10) leads to the equivalent inequality given by

$$
\begin{equation*}
v_{t_{k_{i}}}+v_{\beta_{1}}-v_{t_{k_{i}}}+\sum_{j=k_{i}+1}^{\rho}\left(v_{t_{j}}-v_{t_{j+1}}\right) z_{t_{j}}^{i} \geq v_{\beta_{1}} . \tag{27}
\end{equation*}
$$

Suppose, for contradiction, that $\hat{o}_{i}$ does not satisfy inequality (10) at equality for this choice of $T$. Then, from (27), we see that we must have $\sum_{j=k_{i}+1}^{\rho}\left(v_{t_{j}}-v_{t_{j+1}}\right) z_{t_{j}}^{i}>0$. In other words, there exists $t_{j^{\prime}} \in T$ for some $j^{\prime} \in[\rho] \backslash\left[k_{i}\right]$ with both $z_{t_{j^{\prime}}}^{i}=1$ (i.e., $t_{j^{\prime}} \notin V_{i}$ ) and $v_{t_{j^{\prime}}}-v_{t_{j^{\prime}+1}}>0$. This along with Assumption A3, implies that $v_{t_{j^{\prime}}}>0$. Moreover, from $j^{\prime} \in[\rho] \backslash\left[k_{i}\right], t_{k_{i}}=\bar{j}_{i}$ and the definition of the sequence $T$, we deduce $v_{t_{j}^{\prime}} \leq v_{t_{k_{i}}}=v_{\bar{j}_{i}}$.

Because $t_{j^{\prime}} \in T \backslash V_{i}$, there exists another point, say $\hat{o}_{\ell}=B\left(V_{\ell}\right) \in \widehat{\mathcal{O}}$ or $\hat{o}_{\ell}=C\left(V_{\ell}\right) \in \widehat{\mathcal{O}}$, such that
$t_{j^{\prime}}=\arg \max \left\{v_{j} \mid z_{j}^{\ell}=0, j \in \Omega\right\}=\bar{j}_{\ell}$. Hence, $t_{j^{\prime}} \in V_{\ell} \backslash V_{i}$. We have $\min \left\{\max _{j \in V_{i}} v_{j}, \max _{j \in V_{\ell}} v_{j}\right\}=$ $\min \left\{v_{\bar{j}_{i}}, v_{t_{j^{\prime}}}\right\}=v_{t_{j^{\prime}}}=\max _{j \in V_{\ell}} v_{j}>\max _{j \in\left(V_{i} \cap V_{\ell}\right)} v_{j}$, where in the equations we have used respectively the definitions of $\bar{j}_{i}$ and $\bar{j}_{\ell}$ along with $t_{j^{\prime}}=\bar{j}_{\ell}$, the fact that $v_{t_{j^{\prime}}} \leq v_{\bar{j}_{i}}$. Whenever $V_{i} \cap V_{\ell}=\emptyset$, the strict inequality follows from $v_{t_{j^{\prime}}}>0$ and our convention that $\max _{j \in V} v_{j}=0$ for $V=\emptyset$. Whenever $V_{i} \cap V_{\ell} \neq \emptyset$, recall that if $\hat{o}_{i} \in\left\{B\left(V_{i}\right), C\left(V_{i}\right)\right\}$ is in $\widehat{\mathcal{O}}$ and $\hat{o}_{\ell} \in\left\{B\left(V_{\ell}\right), C\left(V_{\ell}\right)\right\}$ is in $\widehat{\mathcal{O}}$, then from the premise of the lemma, we have $V_{\kappa}:=V_{i} \cap V_{\ell}$ is such that $\hat{o}_{\kappa} \in\left\{B\left(V_{\kappa}\right), C\left(V_{\kappa}\right)\right\}$ is also in $\widehat{\mathcal{O}}$ which implies that the strict inequality above follows from $\bar{j}_{\ell}=t_{j^{\prime}} \notin V_{i} \cap V_{\ell}$, hence $\bar{j}_{\kappa}=t_{k_{\kappa}}$ for some $\rho \geq k_{\kappa} \geq j^{\prime}+1$ and that $v_{t_{j^{\prime}}}>v_{t_{j^{\prime}+1}} \geq v_{\bar{j}_{\kappa}}$. Consequently, we reach a contradiction because this inequality implies $\psi\left(\mathbf{v}, V_{i}, V_{\ell}\right)>0$, which contradicts the premise of the lemma. As a result, $t_{j^{\prime}}$ cannot exist, i.e., $z_{t_{j}}^{i}=0$ for all $j=k_{i}+1, \ldots, \rho$ in inequality (27). Hence, inequality (10) for this choice of $T$ must be tight at any solution $\hat{o}_{i} \in \widehat{\mathcal{O}}$ satisfying the premise of the lemma.
